The CHAIRMAN said that that was so, and it was fully explained at the last meeting, and the shareholders thought they would be very well off if they got the contractors to accept payment in that manner.

Mr. COCHRANE asked whether they had paid more for the cable than if it had been paid for in cash.

The CHAIRMAN replied that they had got the cable on more advantageous terms than they could have got it from any other company, and the price had not been increased on account of the payment being made in debentures. There was nothing whatever added on the score that the Construction Company was taking payment in debentures, and they had got the cable on quite as advantageous terms as if they had been in a position to pay cash, which the shareholders knew they were very far from being in.

Mr. COCHRANE thought that some of the shareholders had come to the conclusion that a larger sum had been paid for the cable on account of the deferred payment, which was not an unusual condition.

The CHAIRMAN: That is not so.

Mr. BEARD pointed out that there had been a very steady advance in the expenses. As a tolerably old shareholder he must say that he had lived to a large extent on hope, and that hope had been disappointed. He doubted very much whether the prognostications of the chairman, with the addition to their capital, would be fulfilled. No doubt their arrangements with the Eastern Company would work comfortably, and they would be able to give the Company most substantial support; but whether the prognostications of the chairman were likely to be fulfilled he could not say.

The CHAIRMAN said that he had not held out any exaggerated expectations, but had given the figures on which his calculations were based, and concluded by saying that, so far as he could see, there was a fair prospect of a moderate dividend coming to the ordinary shareholders.

The motion for the adoption of the report was then put, and carried unanimously.

A dividend at the rate of 10 per cent., less income tax, was declared on the preference shares for the half year ended 31st December, 1883.

Messrs. Bannatyne and Etlinger, the retiring directors, were re-elected, and Mr. Herbert R. Duke, the retiring auditor, was reappointed.

A vote of thanks to the chairman and directors terminated the proceedings.

## THE GERMAN UNION TELEGRAPH AND TRUST COMPANY (LIMITED).

Report of the directors to be presented to the thirteenth ordinary general meeting of the shareholders, to be held at the offices of the Company, at 66, Old Broad-street, E.C., on the 3rd April, at 12 noon:—The directors beg to submit the accounts and balance sheet for the twelve months ending 31st December, 1883, including in the accounts the coupon in respect of that date just received from the German Union Company of Berlin. The total receipts during the twelve months amount to £12,635 11s. 8d., which, with a balance of £41 4s. brought forward from last account, make a total of £12,676 15s. 8d. The expenses for the same period amount to £813 8s. 1d.; of this sum £750 is provided by the German Union Company of Berlin, leaving only a balance of £63 8s. 1d, to the debit of this Company for working expenses. Out of the receipts an interim dividend of 5s. 9d. per share was distributed on the 19th January last, and the directors recommend the payment of a further dividend of 6s. per share, making a total distribution for the year of 11s. 9d. per share, free of income tax, or at the rate of £5 17s. 6d. per centum per annum (as against £5 5s. 10d. paid last year), leaving a balance of £1 15s. 1d. to be carried over to the next account. The cables of the Berlin Company and the whole technical apparatus are in good condition, and no material interruption took place in the year 1883. The storms in the spring of that year, however, destroyed the Company's cable house at Lowestoft, which was encroached on by the sea. A new cable house of a substantial kind has been erected, and its capacity is adequate for the purposes of a repeating station, which will improve the telegraphic communication between Great Britain and Germany. The improved working order of the Company's telegraph station at Emden has led to a substantial increase in the traffic. It is satisfactory that, after providing for the Five-and-a-Half per Cent. Preference Stock of the Berlin Company, there is sufficient to enable an enhanced dividend to be paid on their ordinary stock, and, consequently, on the shares of this Company. The reserve and renewal funds of the Berlin Company now amount to £42,500. In addition to this, they have a balance of unexpended capital in hand amounting to £20,500. According to the Articles of Association, Mr. H. G. Erichsen, one of the directors of the Company, retires by rotation, and being eligible, offers himself for re-election. The auditor, Mr. Henry Dever, also retires, and offers himself for re-election.

„ Paper ..... „ 2s. 0d.
Postage 3d. extra.

CONTAINS

**Useful Information relating to Dynamo Machines, and Arc and Incandescent Lamps,**

**Special Formulæ and Tables relating to Electric Conductors and their Cost,**

**A Directory of Electricians,**

**Manufacturers of Electrical Apparatus, &c.,**

**Electric Light Companies,**

**A List of the Local Authorities in Town and Country, with their Officials.**

**Foreign Telegraph Tariffs,**

**A List of Cable Ships,**

**And other Information of Practical Utility to Electrical and Telegraphic Engineers, Electricians, and others.**

## NOTES.

THE MAGAZINES.—*Chambers's Journal* for April contains an article entitled "Curiosities of the Electric Light."

BRADFORD.—Mr. Alexander Moir, late of Edinburgh, is now superintendent of telegraphs for the Bradford district.

NEW BOOK.—Messrs. Spon announce the publication of Mr. J. J. Fahie's "History of Telegraphy to the year 1837."

APPOINTMENT.—Professor W. Garnett, of University College, Nottingham, has been appointed Principal and Professor of Mathematics in Durham College of Science at Newcastle.

SIAMESE TELEGRAPHS.—A telegram has been received at the Siamese Legation announcing that the new telegraphic route to Bangkok, *vid* Tavoy, was opened on the 21st of last month.

ZANZIBAR MOZAMBIQUE CABLE.—This cable, which was interrupted a few days ago, is now repaired, and messages for South Africa can now be accepted by the Eastern Telegraph Company.

GRECIAN ARCHIPELAGO.—We understand the Eastern Telegraph Company is about to connect the various islands of this group by means of cables on the terms of a subsidy with the Greek Government.

BRAZILIAN SUBMARINE CABLE COMPANY.—The duplicate cable of this company's system between Madeira and St. Vincent has been successfully completed, and the cable between St. Vincent and Pernambuco repaired.

HELL GATE LIGHTHOUSE, NEW YORK.—The Brush Company of Cleveland is about to supply dynamos and lamp, the latter to be placed on the top of a lattice girder structure, 250ft. high, to illumine the entrance to the New York harbour.

EARTHQUAKES IN CROATIA.—Strong shocks of earthquake were felt in Agram on the 25th and 26th ult. Shocks have also been felt in many places in the province of Sclavonia. At Diakovar several buildings and nearly all the dwelling houses have sustained damage.

FRENCH ELECTRIC POWER AND STORAGE COMPANY.—Messrs. Woodhouse and Rawson write, with reference to our note stating that they had petitioned for the winding up of this company, to say that the petition has been withdrawn, their claim having been paid in full.

DIRECT SPANISH CABLE.—The Eastern Company's ss. "Volta," after having successfully found and repaired two faults in this cable, had to put into Falmouth under stress of weather. The ship is now engaged upon the last fault, and it is hoped the cable will be in use again immediately.

ELECTRIC LIGHTING AT WIMBLEDON.—The experiments in street lighting by means of incandescent lamps, which Mr. Preece mentioned some few days ago as about to be carried out at Wimbledon, are now being made. Overhead wires are used, and about one mile and a half of streets are lighted.

THE WERNER LAMP.—We are informed that Messrs. Clark, Muirhead and Co., Regency-street, Westminster, have been appointed sole manufacturers and agents in the United Kingdom for the Werner arc lamp, which is said to be of very simple construction, and well known on the continent.

THE BERBER TELEGRAPH CLERKS.—The correspondent of a daily paper telegraphed from Cairo on Tuesday night that the telegraph clerks at Berber had wired a joint message to the Khedive, stating their wish to leave their present post, which they said had become an extremely dangerous one to hold.

TOWER OF LONDON.—On the 26th ult. the lighting of a portion of the armoury of the Tower of London by six Pilsen arc lamps of 2,000 nominal candle-power each, driven by one of the Pilsen Company's dynamo machines, was witnessed by Colonel Festing, R.E., and a number of the members of the staff of the Royal Engineers, &c. The lighting was a complete success.

ELECTRIC LIGHTING IN LEEDS.—The Leeds papers are very indignant with the electric lighting committee of the Town Council for their dilatoriness in not having so arranged matters that the electric light would have been ready for the opening of the new municipal offices. The blame is laid on the gas committee as having put every possible obstacle in the way of the introduction of the electric light that they could.

THE TELEGRAPH STATION AT SUAKIM.—The *Standard's* correspondent at Suakim telegraphs as follows:—"The Eastern Telegraph Company have secured suitable premises for their staff, and for a permanent office. The correspondents here and the public at home are equally under obligation to them for the admirable and efficient service they have provided. On one occasion as many as twenty thousand words were tendered after sundown, and of these messages all London had the benefit next morning."

UNDERGROUND WIRES IN PHILADELPHIA.—The Pennsylvania Railroad Company have adopted the underground system for all but two of their forty odd wires in Philadelphia. These run between their Broad-street Station, the main office in South Fourth-street, and the freight station in Front and Walnut-streets. The wires are laid in conduits filled with oil according to the patent of Mr. David Brooks, of Philadelphia, whose system is well known as having been successfully tried here. The effects of induction are but very slightly felt, though telegraph, telephone, and even electric light wires are laid in the same tube.

TELEGRAPH EXTENSION IN ORKNEY.—It is stated as probable there that the telegraph will shortly be extended to three of the principal fishing stations in Orkney—namely, Holm, Burray, and St. Margaret's Hope. The Post Office department has agreed to reduce the guarantee from over £600 to £298, and the Fishery Board has agreed to guarantee this amount on the condition that those locally interested make up one-third of the deficiency they may be called upon to pay. Steps are consequently being taken to get the amount to cover the deficiency subscribed, so that the erection of the line may be proceeded with as soon as possible.

THE GIANT'S CAUSEWAY RAILWAY.—A telegram to a Dublin paper, dated Londonderry, Friday, the 28th ult., says:—"A rather mysterious affair has happened in connection with the insulated electric railway on the Giant's Causeway and Portrush Tramway. It appears that the country people are in the habit of touching the rail and receiving harmless shocks; but on Thursday evening a ploughman, returning with his horses, stood on the rail to mount. Immediately on his applying his hand to the horse's back the brute fell dead against the rail. The strange part of the affair is that the man was uninjured, although the current passed through his body to the horse."

RIVER PLATE TELEPHONE COMPANY.—The following gentlemen have been elected directors of this company:—Alexis Mols, Esq., director of the Bell Telephone Manufacturing Company (Limited), and of the Compagnie Belge du Téléphone Bell, Antwerp; Edward Weber, Esq., merchant,

Digitized by Google

131, Wool Exchange, Coleman-street, London, and 3, Cité Trévise, Paris. The resignations of the chairman, Major Alexander Wood, and of R. M. Cunningham, Esq., and Edward Zimmermann, Esq., directors, have been received and accepted; Frank W. Jones, Esq., managing director, has been elected chairman; and the offices of the company have been removed to No. 131, Wool Exchange, Coleman-street, E.C.

Bethnal Green Museum.—On Wednesday last, the 26th ult., a most successful inauguration of the electric light took place at the Bethnal Green Museum, when there were present Colonel Festing, R.E., representing the Science and Art Department, and several of the directors of the Pilsen, Joel, and General Electric Light Company, the latter being the contractors for the work. The installation consists of twenty-eight Pilsen arc lamps of 2,000 nominal candle-power each, and 318 Gatehouse incandescent lamps of 20 nominal candle-power each, the motive power being derived from two 16 horse-power stationary coupled engines, with multitubular loco-type boiler, by Messrs. Hornsby and Sons, of Grantham. The work has been carried out in a most satisfactory manner, and reflects great credit on the contractors, in whose factories at Kentish Town the whole of the electrical plant, including dynamo machines, lamps, &c., has been manufactured.

Chesterfield and the Electric Light.—A public meeting was held at Chesterfield a few days since to take into consideration the public lighting of the town. The mayor presided, and said that he considered the town had been efficiently lighted for the past with the electric light.—The following resolution was moved by Mr. J. Warner, and seconded by Councillor Moffat:—"That in the opinion of this meeting the lighting of the town by electricity, after a trial of two and a half years, is unsatisfactory, and calls for the serious consideration of the Town Council with the view of substituting some better and cheaper mode of lighting." An amendment was moved by Mr. Jas. Gill as follows:—"That this meeting wishes to continue the use of the electric light, believing it to be better than gas, and that the mayor be requested to convene another meeting on the subject." On the two motions being put to the vote the amendment was declared to be carried by an overwhelming majority.

Death of an Electrician.—Dr. Maurice Vergnes, inventor and electrician, died on March 2, at No. 64, Clinton-place, New York, after a short illness. He was born in Besançon, France, in 1800, his father being at the time one of the generals of Napoleon I. He graduated, says the *Electrical World*, from L'Ecole Polytechnique, in Paris, and subsequently was appointed inspector of public works and of theatres. In 1830 he left Paris, and gradually drifted around the world. Some years later he settled in St. Louis, and was known there as an architect of ability. He also published a scientific paper in that city, in co-partnership with Cortambèrc, the scientist. He subsequently came to this city, where he pursued the occupation of an inventor with much success. He obtained numerous patents for electrical and mechanical apparatus. At the time of the Crystal Palace Exhibition in New York he displayed an electrical machine of his invention which attracted much attention. Of late years he has patented several devices in connection with steamship machinery. His death was due to the exhaustion of old age.

Electric Lighting in Spain.—A Barcelona correspondent writes:—"At the general meeting of the Sociedad Española de Electricidad, held in Barcelona on the 21st inst., it was stated that up to the present the company had installed in Barcelona and other places 700 arc and over 1,000 incandescent lamps, the working of which gave perfect satisfaction. The amount received for articles made by the company in 1883 and sold reached the sum of pesetas 782·734 and 22 centimos, the profits being pesetas 128·419,53. It was agreed to convert the Junta de Inspeccion into Junta de Gobierno, to reduce the capital of the company by one half of its nominal value, and to accept the resignation of the managing director, D. Tomás José Dalman, who is nominated consulting electrician to the Junta de Gobierno. As the above decisions change essentially the original statutes and rules of the company, it was decided to form new ones, and for this purpose both documents were read to the shareholders, and, after a detailed discussion, approved. It was also agreed to stamp on each of the shares issued by the company a note stating that the nominal value represented was reduced by one half.

Electric Lighting for Lighthouses.—The following notice has been given by the Trinity House with reference to the experiments with gas, oil, and electricity as illuminants for lighthouses at the South Foreland:—"After the 3rd April the exhibition of the experimental lights at the South Foreland will be commenced; and they will be visible at irregular periods, probably every night (except Sunday) during the ensuing six months. These lights will be shown from three temporary wooden towers, respectively marked A, B, and C, 180 feet apart, placed in a line bearing N.W. from the high lighthouse, the distance between the high light and first experimental light (A) being 245 feet; consequently, the present permanent high and low lights are to seaward of the experimental lights. The existing electric lights from the high and low towers will not in any way be changed or interfered with. The centre of each experimental light is about 15 feet below that of the permanent high light, and the lights to be shown from the former will necessarily have varying characteristics which cannot be stated definitely. The full strength of the experimental lights will be visible to the northward of South Foreland within the bearing from ship of W.S.W. into the land, and to the southward within the bearing of N.E. by N. in towards the land; but doubtless a considerable amount of reflected light will be visible outside these limits."

A Home-made Electric Pen.—A description has been given by Dr. J. Garel of a simple way to make an electric pen, to be used for multiple copying of letters or drawings, to the same effect as the somewhat costly Edison pen. A tracing of the drawing to be copied is taken on thin paper, which is then laid upon a piece of common gas carbon. The larger the carbon in proportion to the paper the less shifting will be required; but a piece of reasonably convenient size may be easily found, and it should be ground to a fair surface. The plate of carbon thus prepared is to be connected with one of the screws of a small induction coil, such as that used for an electric bell. The style for following the design, says a contemporary, is nothing more than a lead pencil, rather hard, and brought to a fine point. The other end of the lead of the pencil is connected by a wire with the other screw of the induction coil, which, in turn, is connected with a suitable battery. The wood of the pencil effectually insulates the current from the operator's hand. The arrangement being thus completed, all that is necessary is to follow the design, or to write the letter upon paper resting on the block of carbon, leaning lightly upon the pencil. As the graphite point proceeds a continuous succession of small sparks flow between it and the carbon; and the intervening paper is accordingly perforated by an infinite number of small holes, burnt by the sparks. These holes are barely visible to the naked eye, except by holding up the paper to the light; but they can be utilised for transferring the design or writing to paper, either

Digitized by Google

by dusting on a powder or by passing an inked pad over the perforations when laid on the recipient.

A NEW USE FOR THE TELEPHONE.—A police-inspector at Odessa, whose name, Dobrjinsky, deserves in spite of its dissonance to be mentioned on account of his cleverness, has discovered a new use for the telephone. One day last week a policeman brought to the station a Jew, having in his possession a quantity of silver believed to be stolen. The silver was in a semi-molten condition, and had none of its original features remaining to assist in its identification. Hence, as the Jew stoutly declared the metal to be his own property, the police-inspector was put in a fix, from which all his cross-examination of the presumed thief failed to extricate him. At last a bright idea struck him. He went to the telephone in the adjoining room, and, mentioning to the officials at the police master's office what had happened, instructed them to utter in solemn tones, on a signal being given, the words —"Itsno Smeliansky, it will be better for thee to confess that thou hast robbed somebody, otherwise thy punishment will inevitably be more severe." Afterwards, summoning the Jew into the room, he pointed to the instrument on the wall, and told him that it really did not matter whether he divulged his crime or not, as the "machine" would do it for him. At this the Jew laughed outright, while the inspector placed a sheet of paper on the table, and prepared to take down the confession. When everything was ready he told the Jew to put the tube to his ear, and decide whether he would confess himself or allow the "machine" to do it for him. Then, giving the signal, he returned to the table, when he had the satisfaction of seeing the Jew's face turn deadly pale at hearing the solemn advice conveyed to him by the "machine," and of noting down directly afterwards a penitent confession.—*Globe*.

TELEGRAPH EXTENSION IN SCOTLAND.—A large deputation of Scotch fish merchants and fish curers waited upon the Fishery Board on the 26th March, with the view of obtaining their assistance in approaching the Government in connection with telegraphic communication to Castlebay, in Barra, Scotland. The deputation was introduced by Mr. Bilton, W.S., and was accompanied by Mr. Ranald Macdonald, Cluny Castle. Mr. M'Combie made a statement to the board explaining the objects of the deputation, which are to have the telegraph extended to Castlebay without the necessity of the large guarantee which the Post Office demands. He referred to the growing importance of the place as a fishing station, and the crying necessity for telegraphic communication. He also explained that as a very large part of the telegraph revenue of the country is contributed by the fishing interest, it is not fair to those concerned in that industry to burden them with a guarantee for a station which may not pay at the outset. He submitted that the surplus revenue of other stations should be held to meet any deficiency which may at first arise at Castlebay. Mr. M'Combie also pointed out that the question is a national one, inasmuch as it concerns the national food supply, and that the increase in the fishing industry which would follow additional telegraphic facilities would greatly benefit the crofter population; indeed, that this was one of the means of benefiting the people suggested to the Crofter Commission. He also pointed out that the herrings caught at Castlebay are the best caught round the British coast, and are principally sent to the Continent salted, mainly in consequence of the want of telegraphic communication. The board expressed their gratification at seeing the question taken up by so influential a deputation. The deputation afterwards proceeded to London, where they are to make a representation to the Postmaster-General.

ELECTRIC LIGHTING IN OFFICES.—Messrs. Sir W. G. Armstrong, Mitchell, and Co., of Elswick, Newcastle-on-Tyne, have recently had their Ordnance drawing offices fitted up with incandescent lamps by the Edison and Swan Co. There are 120 Swan lamps in use, of the high resistance class, with ground globes. The dynamo used is one of Messrs. Siemens' self-regulating machines, and it is driven by the powerful Corliss engine which drives the machinery in the large Ordnance workshop. The electric lamps have replaced an equal number of gas jets; and Messrs. Armstrong, Mitchell, and Co. are so well pleased both with the improved light and the coolness and purity of the air of the room (which before the introduction of the electric light was sometimes almost unbearably vitiated) that they have decided on lighting their new engineering offices with Swan lamps. The Edison and Swan Company have also fitted up for this firm an apparatus for lighting the inside of the barrels of the guns after they are bored out. By its means the whole bore of the gun can be carefully examined to see that the forging is perfectly sound. The apparatus consists of a framework fitted to the required diameter varying from 21in. down to 2in. or 3in., and carrying one or more Swan lamps, with a sheet of silvered glass placed at such an angle that an image of a portion of the side of the gun can be examined from its mouth; by moving the apparatus each portion can be examined. The current for this apparatus is generated by a small self-regulating dynamo, and wires are conveyed from it to the various shops. In these a number of specially-designed slip connections and switches are provided at convenient distances apart, and the flexible cords attached to the sliding frames can be connected to whichever of them happens to be nearest the gun which has to be examined. The flexible cord is secured to the frame by a simple connection which will fit any of the frames. The electric light has also been utilised very successfully for taking photographic prints of large drawing plans at night or on dark days. The various apparatus used in this installation have been designed by and the work carried out under the superintendence of Mr. John W. Edmundson, C.E., of Newcastle-on-Tyne, who now has charge of all the Edison and Swan United Company's land installations in Scotland and the northern counties of England.

THE WESTERN ELECTRIC COMPANY IN CHICAGO.—An American paper gives the following description of the new works of the Western Electric Company in Chicago:—"The building, situated at the corner of Clinton and Van Buren-streets, is of brick, with white stone trimmings, four stories and a basement high, 350 feet by 50. There is a blacksmith's shop adjoining, 20 × 40, and an engine room, 40 × 50, and the total floor space is 100,000 sq. ft. The company own the whole lot, and at their present rate of progression will soon have to build all over it. The basement is principally devoted to the manufacture of the Patterson cable, and in one part of it the nickel-plating department has its place. At the north end of the first floor are the executive offices of the company, and the remaining space is used for store rooms and the shipping department. In the wing is the woodwork department for the Gilliland switches and the magneto bells. On the second floor is the main machine shop, and in the wing is the general woodwork department. The third floor is taken up by the general machine shop, and in the wing all the insulated wire is manufactured. The fourth floor serves as an assembling room for the Gilliland switches and magnetos, and for the multiple switch-board department. In the wing is the japanning and finishing room. The engine room is the pride of the whole establishment, and deservedly. The engine, of 350 horse-power, was built specially for the company by C. H.

Digitized by Google

Brown, of Fitchburg, Mass., and has a 25-ton driving wheel. The three 100 horse-power boilers were made by the Union Boiler Works of Chicago, and the Butman furnaces by the Butman Furnace Company, of Cleveland, O. The engine is a splendid piece of work, and the handsome fittings of the engine room are appropriate to it. The cost of the building, inclusive of the land, was 160,000 dollars. It was one year in course of erection. It could not be better situated for shipping, as there are five freight depots close at hand, and it is also extremely convenient for visitors, five car lines passing the door. The building is lighted up by electricity, the company making and using a machine of the Siemens type and a lamp invented by Mr. C. E. Scribner. Each floor is in three sections, or rooms, fireproof and connected by iron doors. There are three separate stairways, or fire-escapes, and three steam elevators. On each floor are two safety vaults for keeping books, work material, &c. The building is protected against the spread of fire by automatic mercurial fire alarms of the company's own manufacture. They are put up in the ceiling, and when the temperature rises to a certain height a warning is given. Electric watch-clocks are stationed throughout the building, and the water-tanks have electrical attachments acting in such a manner that the engineer is always kept informed of the height of the water in the tanks."

THE TELEPHONE AND TELEGRAPH IN AMERICA.—The only drawback to statistical returns of all kinds, and particularly when they assume the proportions of a census, is that they are issued to the public so late after the date to which their figures relate. Thus the American census for 1879-1880 was only issued towards the end of last year. We think some of the figures relating to telegraphs and telephones may, however, be interesting, even though they are three years old. And first as to telegraphs. It appears that there were in the United States in 1879-80 110,726 miles of telegraph lines having a total wire mileage of 291,212, and 12,510 stations or offices. The total number of operators employed was 9,661, of whom about 7,000 were employed by the Western Union Telegraph Company alone. In addition to these, the telegraph companies gave employment to 172 general officers, 165 general office clerks, 2,469 messengers, and 2,641 line-repairers and other *employés*, making a grand total of 14,928. The number of poles erected during the year is given as 248,348. The number of companies amongst whom these figures have to be distributed is 77, but the great majority of them owned little lines needing only half a dozen, or in some cases only one or two operators, and having between two and twenty miles of line at work. The number of messages transmitted during 1879-1880 was as follows :—For the Press, 3,154,398, and for other parties, 28,548,783, or a total of 31,703,181. It appears, however, that twenty-seven out of the seventy-seven companies made no report as to the number of messages they had sent. It is probable that these were the smaller fry, and that their figures would not have made any very great difference to those given above. Turning now to telephones, we may make the following extract from the "Remarks" preceding the figures in the census :—"It is of the first importance to remember that the census year 1879-80 was the year in which the telephone business passed through the stages of an unprecedented development. At the beginning of that year this business amounted to little or nothing; at the end of the year it represented one of the great interests of the country. Neither the census nor any other statistical agency can deal in a wholly satisfactory manner with anything which is subject to rapid and violent changes. The tables exhibit 148 companies and private concerns, which aggregate 34,305 miles of wire, 54,319 receiving telephones, and 3,338 *employés*. Of this aggregate number of companies 74 make a complete set of reports as required by the Census Office, including assets, receipts, equipment and service account, and *employés*. The 74 companies reporting assets have 26,764 miles of wire, and 2,630 *employés*, while the 74 companies which omitted to give their assets have only 7,541 miles of wire, and 708 *employés*. There are 132 companies with 32,734 miles of wire and 3,104 *employés* which report receipts from messages sent, &c., leaving 16 companies with 1,571 miles of wire and 234 *employés* which omitted to report receipts or finances." With these remarks in mind the following figures may be taken for what they are worth :—"The total length of wire was 32,734 miles, the total receipts of the companies amounted to 3,098,081dols., and the total expenditures to 2,373,703dols. The total authorised capital of the companies was 17,386,700dols., and the total amount subscribed for 13,358,720dols." The telephone has not stood still since 1880, and the above figures, if ascertained now, would certainly have to be "writ large."

LIGHTNING AND COLLIERIES.—At a recent meeting of the North of England Institute of Mining Engineers, Mr. Henry White, of the Weardale Iron and Coal Company, read a paper entitled "Remarks on Lightning in the Pit at West Thornley Colliery, on December 11th, 1883." As the subject is an interesting one, we make the following extracts from the paper, a copy of which we have received from the author :—"West Thornley Colliery (which has three times been the site of electrical discharges) is situated about a mile from Tow Law, which is 1,000 feet above the sea level; it is 25 fathoms deep, and is sheltered by a hill on the south side 50ft. high, which commences to rise about 50 yards from the pit, the ground on all other sides being fairly level. The steam boiler chimney was 46ft. high, 12ft. south-west from the engine house, and 68ft. south-west from the centre of the pit. The pulleys are 53ft. from the surface. The ropes are made of plough steel, the cages of steel, the guides or skeats are made of iron rails, secured by wrought-iron buttons, and there are four rapper ropes in the pit, two of which only reach to the bottom seam. There are three ranges of pipes in the pit, viz., a sett of 5in. steam pipes, which are covered with patent composition and lead into a receiver at the pit bottom, and from it to the underground hauling engine which is 40 yards on the south side of the pit bottom. A second range consists of an 8in. rising main, which rests upon a large balk at pit bottom, and a third range of 10in. pipes, which goes into the sump about 15 feet below the flat sheets, and is now used for conveying exhaust steam to bank. About 10 p.m. on Tuesday, December 11th, 1883, there was a violent wind, with heavy rain, accompanied with much thunder and lightning. About 10:15 the winding engine brakesman, Mark Adams, who was watching the storm out of the engine house east window, saw a flash of forked lightning about the pulleys, and heard a heavy peal of thunder, and about five minutes afterwards, at 10:20, when still looking out of the window, saw another brilliant flash of forked lightning strike the pulleys and light everything up in a blaze, almost blinding him, instantly accompanied by a terrific clap of thunder. Hearing a great noise on the other or west side of the engine house, he opened the door and found the boiler chimney had been struck at the top on the north-west side, and a large zigzag rent made on the west side, varying in width from a few inches to two feet, and reaching to within about 15 feet from the bottom, and bricks and lime were falling all over the place. Robert Emery, the master shifter, who was engaged about three yards from the

Digitized by Google

shaft bottom, said he heard brattles of thunder about 10 o'clock, and between that and 10:20 he heard a very heavy one, when at the same time a flash of lightning came down the pit on the south-west side, and apparently down the rapper rope, glancing from the rapper handle, which pointed at an angle of 45 degrees towards the 5in. steam pipes, which were about 3ft. off, and uncovered at that point, and producing a brilliant light and a noise like that of the firing of a gun. There are metal flat sheets on both sides of the pit. There were no marks of damage about, but the flash seemed to have left behind a sort of vapour which appeared to pass along the steam pipes inbye, and it may be assumed that the lightning struck the pulleys and went down the winding rope to the cages, which were standing in the shaft, and then passed to the rapper rope." After referring to other instances in which this same pit had been struck, the author says:—"Having had some conversation with Mr. Massingham, Dean-street, Newcastle, who has had large experience in putting up lightning conductors, &c., the writer asked him if he knew of any local reasons why this pit should have been so often struck, and he replied that when once a place had been struck by lightning it was rendered more liable to be struck again for some time after, and that some parts of the earth, owing to the nature of the soil, &c. (which at West Thornley was a wet bluish clay probably with metallic veins running through), had a greater affinity for lightning than a dry soil of sand, chalk, or granite. When asked as to the area or space a conductor would protect, he said it was now generally agreed that the area protected was in the form of a cone whose base was equal to its height, so that it would appear all chimneys or buildings a certain distance apart should have a separate conductor; and he was of opinion that the lightning, being forked, had struck the West Thornley chimney and pulleys simultaneously, and that a conductor on the chimney would not in all probability have prevented the lightning going down the pit. The pit being an upcast, the warm current of air would offer a great inducement to the lightning. All lightning conductors should be tested about once a year, as, owing to alterations, repairs, and earth connections being disturbed, they are apt to get out of order."

Electric Lighting at Godalming.—This little town has for some time past been lighted, by means of incandescent and arc lamps, by Messrs. Siemens Brothers and Co. In fact it was one of the first towns in which the electric light was adopted on a permanent scale. The Town Council held a special meeting a few days since to consider future arrangements as to the lighting of the town, the council being apparently divided on the question of whether gas or electricity should be used. The lighting committee reported that they had been in communication with several companies. The gas company offered to light the borough on the following terms:—Using 5 feet per hour burners, £3 16s. 5d. per lamp per annum; 6 feet ditto, £4 10s. 2d.; 7 feet ditto, £5 3s. 10d.; Bray's 100-candle lamp, to be reduced to one burner of 5 feet at 11:30 p.m., £9 6s. An immediate expenditure of £134 16s. would be required for new lamps, &c., and the annual cost would be £270 10s., as, if gas was adopted the 6ft. burner should be used. Four electric light companies were communicated with, but their terms were not suitable. Messrs. Siemens were willing to continue for another year on the same terms, provided the Corporation applied for a license under the Electric Lighting Act, 1882, and secured the same to the company. The same outlay was required as in the case of the gas supply, and the committee recommended that seven new lamps be erected.—Alderman Stedman said if the Corporation took out a license and handed it over to Messrs. Siemens the Corporation might be placed in a serious difficulty. The license would last for seven years, but if at the expiration of two years the company to whom the license was handed over declined to go on any further he believed any consumer might call upon the Corporation to supply them with electricity. That would place the Corporation in a very unfavourable position. If Messrs. Siemens would take out the license themselves, with the full consent of the Corporation, there could be no objection to it; but he saw very serious objections to the Corporation taking out the license, and incurring responsibility in the event of failure. Some conversation then ensued, in the course of which it was suggested that Swan lamps of double the lighting power of those at present in use should be introduced. Mr. Alex. Siemens was then called into the room, and in reply to questions said his company had not the slightest objection to taking out a license; but the Board of Trade had made a rule not to grant licenses except to the local authority. He had called at the offices of the Board of Trade, and they had promised to give full consideration to any special reasons that might be adduced for making an exception in the case of Godalming. Up to the present time the company had lost money in Godalming, and they had not cared to extend so as to make it pay them, because the contract was only for one year. Now they felt they had learned everything they could from the present mode of carrying it out they would like to extend it, but felt they would not be justified in doing so except on a legal footing. Being asked whether his company would go on with the public lighting as before if they got the licence, Mr. Siemens said that would depend upon the probable extension of the light. Their present machinery was sufficient to supply 320 incandescent lights, and if they were all burning it would cost—apart from interest on capital—over £600; and they would only be receiving £640 for it, so that it was at present simply a losing business. If they could get 400 or 500 private lights the public lighting would be of secondary importance.—Alderman Stedman said the committee had recommended the abolition of the arc lights, and an increase in the power of the Swan.—Mr. Siemens said that would please him very well, for the arc lights are at present a source of great loss. He would arrange for some more powerful lamps to be put up to show the effect. The present Swans were nominal twenty candle-power. With the present apparatus they could work a good many more lamps than at present. The more lamps the public took the cheaper would each separate lamp become. If 320 lamps were burning they could do it at £3 per lamp. If they could put up bigger plant, and get up to 1,000 lamps, they could do it at £2 per lamp. At present there were only 160 lights going. But they had never tried to extend the trade, so that the first thing he should like to do would be to ascertain how many people would be likely to take the light. As they commenced the light in Godalming, they were prepared to do a good many things to keep it going; but they must see their way to make both ends meet, otherwise it was not commercially right; because a penny loss would throw the whole thing over, and would not justify them in continuing the light. He did not know the general feeling about the light. If, after canvassing the town, they found that there was a reasonable chance of supplying such a number of houses as would secure them a profit they would supply the increased Swan lights at £3. They did not look to their concern at Godalming to live upon. Eventually the meeting adjourned to allow Mr. Siemens to canvass the town to ascertain if it would be worth his while to continue the lighting, and also to allow him to obtain further information from the Board of Trade with regard to the license.

## ELECTRO-CHEMISTRY.—INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 463.)

**Electrolytic Sounds.**—By employing as an electrolyte a solution of potassio mercuric cyanide, with electrodes of the liquid metal, I discovered that the mercury emitted electrolytic sounds, and became covered on its surface with minute waves, symmetrically disposed, and beautiful in appearance. These waves and sounds appear to be due to the rapid alternate formation and destruction of films upon the mercury by electrolytic action. The best solution for producing it consists of 10 grains of mercuric cyanide and 100 of pure potassic hydrate dissolved in $2\frac{3}{4}$ ounces of aqueous hydrocyanic acid of "Scheele's strength," and the liquid filtered. The waves and sound occur at the cathode. The mercury may be contained in two small watch glasses submerged in the solution contained in a large, flat bottomed glass basin. The current employed may be from two Grove's or five Smee's elements, and conveyed into the electrodes by platinum wires protected from the electrolyte by means of glass tubes. By suitable tests I found that during the emission of the sounds the electric current was rendered to a considerable extent intermittent, and that the arrangement might be employed for similar uses to those of a voltaic break-hammer; the intermittence, however, is much less perfect. (See *Proc. Roy. Soc.*, 1861 and 1862.)

For the detection and estimation of mercury by electrolysis, see F. W. Clarke, *Jour. Chem. Soc.*, Vol. XXXIV., 1878, p. 916; also Vol. XXXVI., 1879, p. 976; J. Lefort, *ibid*, Vol. XXXVIII., 1880, p. 510; Watts's "Dictionary of Chemistry," Vol. VIII., part 2, p. 1,277. J. B. Hannay estimates mercury electrolytically by passing a current through a solution of its sulphate into a platinum dish containing it.

**Separation of Copper.**—Cu. Atomic weight = 63·5. A dyad cation. By simple immersion of magnesium in a solution of cupric chloride, Brunswick green, but no metallic copper, appears; but in one of cupric sulphate, the metal, together with its hydrated protoxide, and a green subsalt are produced (Commaille, *Chem. News*, Vol. XIV., p. 188). From a solution of cupric nitrate or sulphate, aluminium after two days' immersion deposits copper; in the nitrate solution a green basic salt of copper is also produced; but if a minute amount of alkali chloride is added to either of these liquids, deposition commences at once. From a solution of cupric chloride or acetate, aluminium separates copper at once, but the deposition afterwards proceeds slowly (A. Cossa. Watts's "Dictionary of Chemistry," Vol. VII., p. 54). According to Smee, iron does not decompose a neutral solution of cupric acetate, nor alkaline ones of ammonuret, ammonio nitrate, or ammonio sulphate of copper, but decomposes one of the nitrate. Zinc amalgam deposits copper from neutral solutions of cupric salts, and forms a copper amalgam. (Damour, *Jour. Prac. Chem.*, Vol. XVII., p. 345). By adding crystals of silicon to melted protoxide of copper, I observed that sudden incandescence and a full white heat were produced, and metallic copper was separated. Thallium deposits copper from the solution of cupric nitrate, sulphate, and acetate (W. C. Reid, *Chem. News*, Vol. XII., p. 242). Raoult states that gold in contact with copper, in either a cold or boiling acid or neutral solution of a cupric salt, receives no deposit of copper (*Jour. Chem. Soc.*, Vol. XI., p. 465).

Smee states that the use of solutions of the hyposulphite, ammoniuret, or acetate of copper, with a separate current, offer no advantages for depositing copper, because they are difficult to decompose, and require a current from several cells, that a copper anode is but little corroded in a solution of sulphocyanide of potassium, and the solution does not hold much dissolved metal, also that the anode is very slightly acted upon in a solution of tartrate of potassium. M. P. Schutzenberger found from five to ten per cent. of cuprous oxide in copper electro-deposited from an acetate solution (J. B. Mackintosh, *Chem. News*, Vol. XLIV., p. 279, and Vol. XLV., p. 101).

**Formation of Nitride of Copper.**—By passing a current from six Grove's cells into one end of a solution of salammoniac contained in a long glass trough by means of a copper anode, and out of the liquid at the distant end by a platinum sheet cathode, the liquid becomes blue, and a heavy solid nitride of copper of a chocolate colour collects at the cathode (Grove, *Phil. Mag.*, 3rd Series, Vol. XIX., p. 100).

**Electrolysis of Cupric Nitrate.**—$Cu.2No_3$. Molecular weight = 187·5. I observed that a solution of cupric nitrate yielded its metal to zinc, tin, lead, or iron, by simple immersion, but not to nickel, copper, silver, gold, platinum, or antimony. J. B. Mackintosh states that in the electro deposition of copper from a nitrate or sulphate solution containing citric or tartaric acid, the deposited metal is not pure. With the nitrate solution containing citric acid, electrolysis was attended by a strong odour of hydrocyanic acid (*Chem. News*, Vol. XLIV., p. 279, XLV., p. 101).

**Electrolysis of Cupric Fluoride.**—$Cu.F_2$. Molecular weight = 101·5. I observed that copper was separated from its melted fluoride by adding fragments of magnesium; also that crystals of silicon immersed in a solution of the fluoride evolved gas, and became instantly coated with copper.

By means of a separate current from six Smee's cells, a platinum wire helix anode and a copper wire helix cathode, I electrolysed fluoride of copper, fused at a bright red heat in a deep copper cup. Conduction was copious, as if the salt was a metal, and an acid vapour was evolved. The anode was unaltered, no copper was deposited, but the cathode had lost 3·35 grains in weight by corrosion near the surface of the melted salt; the copper vessel was also similarly acted upon in several experiments and caused to leak. The phenomena were much like those obtained with melted argentic fluoride.

A solution of cupric fluoride in pure dilute hydrofluoric acid, with copper electrodes, conducted freely the current from a single Smee's element, and yielded a good deposit of copper.

**Electrolysis of Cupric Chloride.** — $Cu.Cl_2$. Molecular weight = 134·4. Aluminium acts briskly on a solution of cupric chloride at 16°C, setting free copper, hydrogen, and aluminium oxychloride, the composition of which varies with the temperature (D. Tommasi, *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 1,266; Vol. XLIV., 1883, p. 19; *Chem. News*, Vol. XLVI., p. 62). Copper is at once deposited from its chloride, and more slowly from its acetate by aluminium (A. Cossa, Watts's "Dictionary of Chemistry," Vol. VII., pp. 54 and 383). I observed that in a solution of cupric chloride, bismuth, zinc, tin, lead, and iron deposited copper by simple immersion, but nickel, copper, silver, gold, platinum, or antimony did not; also that in a solution of sub-chloride of copper in strong aqueous ammonia zinc received a deposit of copper by simple immersion, but tin, lead, iron, nickel, copper, silver, gold, platinum, bismuth, or antimony did not. When a copper platinum couple is immersed in a dilute solution of this salt insoluble white cupreous chloride is deposited on both the metals. With couples formed of zinc-platinum or magnesium platinum the action is stronger, and metallic copper is deposited upon the platinum. (Gladstone and Tribe, *Phil. Mag.*, 4th Series, Vol. XLIX., p. 425.)

M. Weis Kopp coats iron with copper by simplo immersing it in a bath composed of 10 parts of cupric chloride, 10 of nitric acid, and 80 of hydrochloric acid of specific gravity 1·105 (*Chem. News*, Vol. XXI., p. 47). According to O. Gaudain, articles of cast iron, wrought iron, or steel may be coated with copper by dipping them into a melted mixture of fluoride and chloride of copper, with five or six parts of cryolite, and a little basic chloride, in a plumbago crucible (*Jour. Chem. Soc.*, Vol. XI., p. 955). In some cases, copper is extracted from sandstone, which contains it in small proportion, by dissolving the ore out by dilute hydrochloric acid, and immersing pieces of scrap iron in the liquid until they are wholly dissolved, and metallic copper is left.

When a feeble electric current is passed by means of copper electrodes through a solution of chloride of copper in dilute hydrochloric acid, the anode becomes covered with snow white crystals of cupreous chloride, and the cathode with a thick deposit of loose copper (*Chem. News*, Vol. XXII., p. 167). If a solution of cupric chloride was electrolysed by a feeble current with platinum electrodes, chlorine appeared at the anode, and cupreous chloride at the cathode; but if the current was strong, metallic

Digitized by Google

copper was also deposited upon the edges of the cathode (Gladstone and Tribe). Smee states that a solution of this salt is less readily decomposed by an electric current than one of the nitrate, but more readily than one of the sulphate, that it is also one of the worst liquids for the electrolytic separation of metallic copper, and that the deposited metal is apt to assume a very peculiar appearance. He also states that a solution of the ammonio chloride is a bad one, having a tendency to evolve hydrogen, and yield a spongy copper deposit; and that one composed of iodide of copper dissolved in aqueous solution of potassic iodide cannot be employed because it liberates iodine. The electrolysis of solution of cupric bromide does not appear to have been examined.

**Electrolysis of Cupric Sulphate.**—Cu. $SO_4$. Molecular weight = 127·5. I have noticed that a solution of cupric sulphate gave up its metal by simple immersion of zinc, tin, lead, or iron, but not to nickel, copper, silver, gold, platinum, bismuth, or antimony. One of the oldest facts in electro-chemistry is the deposition of copper upon iron by immersing the latter in an aqueous solution of cupric sulphate. Vast numbers of steel pens, iron-wire, and other small articles of steel and iron are coated with copper by means of the same liquid slightly acidulated. For coating iron-wire in this way Roseleur used a mixture composed of one part of cupric sulphate and one of sulphuric acid dissolved in from 50 to 100 parts of water. To coat brass with copper, Dr. C. Puscher dissolves 10 parts of cupric sulphate and five of ammonic chloride in 150 of water; dips the clean articles in the liquid for one minute, drains them, and then heats them over a charcoal fire until the ammoniacal salt is expelled, and then washes and dries them (*Chem. News*, Vol. XXIII., p. 215). According to M. Soret, clean copper dissolves in a boiling, saturated, aqueous solution of neutral cupric sulphate, and is deposited in a metallic state on cooling the liquid (*Annal. de Chimie*, Vol. XLII., 1854, pp. 257-277). I have found only a small quantity of red suboxide of copper separate under these conditions. According to Wurtz, pure cupreous hydride can be obtained by the electrolysis of a dilute solution of copper sulphate. (*Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 299.)

Cupric sulphate resulting from the oxidation of cupric sulphide in the earth exists in the water of many mines. Immense quantities of such sulphide are also roasted with common salt to oxidise and render soluble the cupriferous mineral, which is then dissolved out by dilute hydrochloric acid, and the copper in each of these cases is extracted from the liquid by immersing in it scraps of iron. The copper collects as a red powder consisting of small feathery crystals at the bottom of the vats after all the iron has dissolved. Great quantities of the metal are annually deposited in this manner.

Copper is sometimes deposited upon iron by the influence of the contact of a second metal. M. Fred. Wiels uses the following liquid:—Dissolve 150 parts of sodio-potassic tartrate, 80 of soda lime containing from 50 to 60 per cent. of caustic soda, and 35 of cupric sulphate, in 1,000 parts of water. By immersing clean articles of iron or steel in contact with a piece of zinc or lead in this liquid a sufficiently long period of time they receive a strongly adherent coating of copper, of any desired thickness. Pure tin in contact with zinc in this liquid does not become coppered, but oxidises, and its oxide gradually precipitates as red suboxide all the copper of the solution.

Copper is also deposited by means of the contact of two different metals in two different liquids (the "single cell process") for the purpose of coating cast-iron cylinders for calico printing (see *Chem. News*, Vol. XXX., p. 219; also *Jour. Chem. Soc.*, Vol. XIII., p. 196).

A good solution for depositing by means of a separate current is composed of four parts of crystallised cupric sulphate (Cu. $SO_4$, $5H_2O$), and one of sulphuric acid, in 18 or 20 of water. Sometimes sulphate of zinc or of potassium is added to such a solution in order to improve the deposit.

According to A. Long, copper electro deposited by a separate current from a solution of its sulphate contains minute amounts of hydrogen, carbonic oxide, carbonic anhydride, and water. (Watts's "Dictionary of Chemistry," Vol. VII., p. 383)

(TO BE CONTINUED.)

## CLAUSIUS ON THE THEORY OF THE TRANSMISSION OF POWER BY DYNAMO-ELECTRIC MACHINES.

(CONTINUED FROM PAGE 469.)

*2. Determination of the Intensity of Current.*

If the two machines are connected in the ordinary way for the transmission of power, viz., by wires which are under no other electromotive force, the actual electromotive force acting through the whole of the wire is represented by the difference $E_1 - E_2$. Hence, if R is the total resistance of the wire, we may write

$$R\,i = E_1 - E_2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

If in this equation we give $E_1$ and $E_2$ their values, as given in (IV.) and (VI.), we obtain

$$R\,i = \left[\frac{e+i}{(a+i)(b+i)}p\,(v_1 - v_2) - \rho\,(v_1 + v_2) - \left(\sigma + \frac{\lambda}{b+i}\right)(v_1^2 + v_2^2)\right] i \quad . \quad . \quad (3).$$

This equation may be applied to determine $i$.

The first solution of the equation is evidently

$$i = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

After this we may divide the equation by $i$, and then, putting the integral terms on the left side, the equation takes the following form:—

$$R + \rho\,(v_1 + v_2) + \sigma\,(v_1^2 + v_2^2) = \frac{e+i}{(a+i)(b+i)}p\,(v_1 - v_2) - \frac{\lambda}{b+i}(v_1^2 + v_2^2) \quad . \quad . \quad (5).$$

Let us divide this equation by the expression on the left hand, and adopt the following symbols:—

$$\left.\begin{aligned} u &= \frac{v_1 - v_2}{R + \rho\,(v_1 + v_2) + \sigma\,(v_1^2 + v_2^2)} \\ U &= \frac{v_1^2 + v_2^2}{R + \rho\,(v_1 + v_2) + \sigma\,(v_1^2 + v_2^2)} \end{aligned}\right\} \quad . \quad . \quad (6).$$

Then the equation becomes

$$1 = \frac{e+i}{(a+i)(b+i)}pu - \frac{\lambda}{b+i}U \quad . \quad . \quad . \quad . \quad (7).$$

If we multiply this equation by $(a+i)(v+i)$, and then arrange the terms according to the powers of $i$, we obtain a quadratic equation:—

$$i^2 - (pu - \lambda U - a - b)\,i - e\,p\,u + \lambda\,a\,U + a\,b = 0. \quad . \quad (8).$$

Solving this equation, we obtain

$$i = \tfrac{1}{2}(pu - \lambda U - a - b) \pm \tfrac{1}{2}\sqrt{(pU - \lambda u - a - b)^2 + 4\,e\,p\,u + 4\lambda\,a\,U - 4\,a\,b} \quad . \quad (9).$$

Of the two signs to the square root we must, in accordance with the remark made upon the corresponding equation in the former paper, choose the upper; and in applying this positive sign we have the further limitation that the expression only holds for such values of $u$ as are large enough to make it positive. For values of $u$ below a certain limit, which make the expression negative, we must use the value $i = 0$ instead of that given under equation (4). If absolute accuracy is necessary, we should have in this interval not precisely the value zero for $i$, but rather a very small value depending on the remaining magnetism in the fixed electro-magnet of the first, or generator, machine. But this interval only corresponds to velocities in the first machine which occur at starting, and before the second machine has got into motion; hence the small values of $u$ corresponding to this interval have little importance, and we may confine ourselves to the values given by equation (9), which hold for higher speeds of rotation.

We may give this latter equation a still simpler form by introducing the following symbols:—

$$u_1 = u - \frac{\lambda}{p}U = \frac{v_1 - v_2 - \frac{\lambda}{p}(v_1^2 + v_2^2)}{R + \rho\,(v_1 + v_2) + \sigma\,(v_1^2 + v_2^2)} \quad . \quad . \quad (10)$$

$$c = (e - a)\,p = q - p\,a + p\,b \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11).$$

Digitized by Google

The equation then becomes

$$i = \tfrac{1}{2}(p u_1 - a - b) + \tfrac{1}{2}\sqrt{(p u_1 + a - b)^2 + 4 c u} \quad . \quad . \quad (12).$$

### 3. *Comparison of the Quantities of Work Done.*

When we have obtained a definite expression for the intensity of current $i$, the expressions $T_1$ and $T_2$ for the work done, as given in equations III. and IV., are also completely determined, and may be used for calculating the numerical values of these quantities.

To make the formulæ more convenient for comparison, we will first introduce a simple symbol for the term containing the small factors $\sigma$ and $\lambda$, by putting

$$V = \left(\frac{l}{a+i}\right)^2\left(\sigma + \frac{\lambda}{b+i}\right) \quad . \quad . \quad . \quad (13).$$

The two equations then become

$$T_1 = \left(\frac{e+i}{(a+i)(b+i)}p r_1 + \gamma r_1^2\right) i^2 \quad . \quad . \quad . \quad (14).$$

$$T_2 = \left(\frac{e+i}{(a+i)(b+i)}p r_2 - \gamma r_2^2\right) i^2 \quad . \quad . \quad . \quad (15).$$

Further we have, by equation (5)

$$\frac{e+i}{(a+i)(b+i)}p = \frac{R + \rho(r_1 + r_2) + \left(\sigma + \frac{\lambda}{b+i}\right)(r_1^2 + r_2^2)}{r_1 - r_2}.$$

This may be again abreviated by using the following symbol:

$$\delta = \rho(r_1 + r_2) + \left(\sigma + \frac{\lambda}{b+i}\right)(r_1^2 + r_2^2) \quad . \quad . \quad (16).$$

The equation then becomes

$$\frac{e+i}{(a+i)(b+i)}p = \frac{R+\delta}{r_1 - r_2} \quad . \quad . \quad . \quad . \quad (17).$$

By applying this equation, the two equations for $T_1$ and $T_2$ take the following form :—

$$T_1 = \left[(R+\delta)\frac{r_1}{r_1 - r_2} + \gamma r_1^2\right] i^2 \quad . \quad . \quad (18).$$

$$T_2 = \left[(R+\delta)\frac{r_2^2}{r_1 - r_2} - \gamma r_2^2\right] i^2 \quad . \quad . \quad (19).$$

Subtracting, we obtain

$$T_1 - T_2 = [R + \delta + \gamma(r_1^2 + r_2^2)] i^2 \quad . \quad . \quad (20).$$

Dividing equation (18) by (19) we obtain the following :—

$$\frac{T_2}{T_1} = \frac{r_2}{r_1}\cdot\frac{1 - \gamma\frac{r_2(r_1 - r_2)}{R+\delta}}{1 + \gamma\frac{r_1(r_1 - r_2)}{R+\delta}}.$$

If we now develop the fraction containing the symbol $\gamma$ in terms of that symbol, and then neglect all above the first degree (because $\gamma$ contains the small factors $\sigma$ and $\lambda$, whose higher powers have already been neglected in previous calculations), we obtain

$$\frac{T_2}{T_1} = \frac{r_2}{r_1}\left(1 - \gamma\frac{r_1^2 - r_2^2}{R+\delta}\right) \quad . \quad . \quad . \quad (21).$$

These equations (20) and (21) show clearly how $T_1$ and $T_2$ depend upon the velocity of rotation and the intensity of current thereby determined, and also the relations in which they stand to each other. We can use the equations to determine how we should arrange the running of the machines so as to give the most favourable results under any particular circumstances.

On this latter point a rule is often followed which was laid down by M. H. Jacobi in 1840, as to the working of an electromagnetic machine of the old form, driven by a galvanic current. This rule he expressed as follows:—*"The expenditure of zinc when the machine is at rest and does no work is double that which occurs when it is doing its maximum of work."

This rule in an altered form has been applied to the transmission of power by dynamo machines. In this case the velocities of rotation of the two machines have been chosen as the variables for determining the strength of the current and quantities of work done, and the rule has been laid down that the maximum of useful effect will be obtained if the proportion of these two velocities is as two to one.

It must, however, be remarked on the one side that Jacobi drew his conclusion from very inaccurate assumptions, of which the first runs as follows :—"The strength of the magnetism produced in soft iron by a galvanic current is proportional to the strength of that current." Hence we cannot expect any great accuracy in the conclusion itself. On the other side, it must be remembered that his conclusion refers to a strictly definite process, in which a galvanic battery whose working is subjected to fixed laws serves as the source of power; whereas in the transmission of power by dynamo machines other sources of power are employed, and the work done by these may have different relations to the system. Hence, if we are to inquire into the maximum power which can be thus transmitted, we must first lay down precisely the conditions to which this maximum is to be referred.

### 4. *Determination of the Work* $T_2$ *where the Velocity* $r_1$ *is given.*

Remembering the fact just pointed out, that the sources of power which are used for driving the generator machine may have different relations to the system, we will first make the assumption that the source employed is of such a kind that it can give any quantity of work we require. Hence the quantity of work $T_1$ to be used on the first machine is practically unlimited; as, for instance, would be the case if we could employ a natural head of water of great power, which in any circumstances would largely exceed the needs of our machine. We have now to inquire how under the circumstances we may get the greatest possible amount of work $T_2$ out of the second or receiver machine.

If $T_2$ is large, we see by equation (15) that $r_2$ and $i$ must also be large, and the large value for $i$ implies by equation (12) a large value for the difference $(r_1 - r_2)$. Now, the two conditions that $r_2$ and $(r_1 - r_2)$ should both be large can only be fulfilled if $r_1$ is large; hence the first requirement for obtaining a large value of $T_2$ is that $r_1$, or the velocity of rotation in the first machine, should be made as great as possible. Here, however, the mechanical difficulties which are involved in keeping up a very high velocity of rotation confine us within certain limits. We will therefore take the greatest velocity which can be attained in practice as being a given quantity, and make $r_1$ equal to this velocity.

Of the two velocities of rotation, $r_2$ alone remains to be determined, and we may consider the work $T_2$ as a function of these two magnitudes. To determine this function we may use equation (19), which is as follows :—

$$T_2 = \left[(R+\delta)\frac{r_2}{r_1 - r_2} - \gamma r_2^2\right] i^2.$$

Here we may replace $i$ by the expression given in equation (12). The magnitudes $u$ and $u'$, which appear in this latter equation, are by equations (6) and (10) functions of $r_1$ and $r_2$; and hence the whole expression for $T_2$ thus obtained is a function of $r_1$ and $r_2$. Finally, since $r_1$ is given, and $r_2$ alone is taken as variable, we may say that in this manner $T_2$ has been expressed as a function of the single variable $r_2$.

In order to find the value of $r_2$ for which $T_2$ is a maximum, we may use the ordinary method of differentiating $T_2$ according to $r_2$, making the differential coefficient equal to zero, and solving this equation for $r_2$. This method, however, is not without its difficulties, on account of the many and different ways in which $r_2$ enters into the equation; and this difficulty remains even if we simplify the terms which contain the small factors $\sigma$ and $\lambda$ by introducing approximate values. We will therefore content ourselves with performing the calculation for a special case and under certain assumptions, so as at least to obtain a general idea as to the magnitude of the required value of $r_2$. The assumption is that the constant $c$, which is equal to $(e - a)p$, and may therefore be positive or negative, or zero, according to the values of $e$ and $a$, has in this case the

* Report of the British Association, 1840, and *Pogg. Ann.* 51, p. 358, 1840.

Digitized by Google

last-named value zero. The expression for $i$ then takes the simple form

$$i = p\,u^1 - b.$$

We will further neglect in our calculations all terms which contain the factors $\rho$, $\sigma$, and $\lambda$. We may then put

$$u^1 = \frac{v_1 - v_2}{R},\ \gamma = 0,\ \delta = 0.$$

The equation for $T_2$ then takes the following form :—

$$T_2 = R\,\frac{v_2}{v_1 - v_2}\left(p\,\frac{v_1 - v_2}{R} - b\right)^2. \quad . \quad . \quad . \quad (22).$$

Differentiating this equation according to $v_2$ we obtain

$$\frac{d\,T_2}{d\,v_2} = \frac{1}{(v_1 - v_2)^2}\left(p\,\frac{v_1 - v_2}{R} - b\right)(2\,p\,v_2^2 - 3\,p\,v_1\,v_2 + p\,v_1^2 - R\,b\,v_1). \quad (23).$$

If this differential coefficient is equal to zero, one of the three factors which make up the right-hand expression must equal zero. With the first factor this is obviously impossible. The second factor

$$p\,\frac{v_1 - v_2}{R} - b$$

represents the intensity of current $i$, and therefore cannot in this case be equal to zero. We must therefore equate to zero the third factor; and we thus obtain, to determine $v_2$, the equation

$$2\,p\,v_2^2 - 3\,p\,v_1\,v_2 + p\,v_1^2 - R\,b\,v_1 = 0 \quad . \quad . \quad (24).$$

Whence

$$v_2 = \frac{3}{4}v_1 \pm \sqrt{\frac{1}{16}v_1^2 + \frac{R\,b\,v_1}{2\,p}}.$$

If we take the upper sign for the square root, it gives for $v_2$ a value greater than $v_1$, and therefore is inadmissible. Accordingly we must employ the lower sign; and therefore, with a slight transformation, we obtain the following equation :—

$$v_2 = v_1\left(\frac{3}{4} - \frac{1}{4}\sqrt{1 + 8\,\frac{R\,b}{p\,v_1}}\right). \quad . \quad . \quad (25).$$

(TO BE CONTINUED.)

## RECENT PROGRESS IN DYNAMO-ELECTRIC MACHINES.*

By Professor SILVANUS P. THOMPSON, B.A., D.Sc., M.S.T.E.
University College, Bristol.

(CONTINUED FROM PAGE 478.)

Formerly, in a 4-pole machine, four brushes were necessary—as in the Gülcher dynamo and the 4-pole Gramme. Mr. Mordey has reduced the number to two, by the device, firstly, of connecting together those segments of the armature coils which occupy similar positions with respect to the poles; and, secondly, of connecting together, by metallic connections, those bars of the collector which are at the same potential. In the four-pole machine opposite bars are thus connected. Two brushes only are then necessary, and these are 90° apart. Fig. 22 gives the actual diagram of the potentials at the collector. There being 60 sections in the ring, there will be 15 segments of the collector from the negative brush to the positive. The potential rises steadily from the negative brush, and becomes a maximum at the positive brush at 90°, whence it again diminishes to zero at 180°. The bars of the collector being connected, it will be remembered, to those diametrically opposite to them, it follows that the potential will rise from 180° to 270°, precisely as it rose from 0° to 90°, and will again fall to zero in passing from 270° to 0° If the curve from 0° to 180° were plotted again horizontally, we should clearly see how nearly regular the rise and fall is. If from this curve we were to construct another one, in which the heights of the ordinates should correspond to the tangent of the angle of slope of this potential curve—in other words, if we were to differentiate the curve—we should obtain a second curve—the curve of induction. It would show a positive maximum at about 30°, and a negative maximum at about 120°, where the slope up and slope down are steepest in the potential curve. These maxima of induction are situated very nearly opposite the edges of the pole-pieces, on the side toward which the armature is rotating. Apparently the lines of force of the field are the thickest here. In this displacement of the maximum of induction we have, I think, the explanation of the inferiority of the earlier machines with broad polar expansions. In those machines the maximum position of induction was displaced to the very edge of the broad pole-piece, and therefore the induction was sudden and irregular. It is a singular result that while in those machines in which the ring armature is extended cylinderwise there must be wide embracing pole-pieces, in those in which the ring is flattened into a disc shape the pole-pieces must on no account be wide.

The Victoria dynamo is self-regulating, having all the eight field magnet coils doubly wound, with main circuit coils inside, and shunt coils outside. The characteristic of this machine is wonderfully straight. In a "D²" machine, wound for a potential of 60 volts, the following values were obtained :—Open circuit, 58 volts; 10 amperes, 58·5 volts; 20 amperes, 59 volts; 60 amperes, 59·7 volts; 90 amperes, 59·9 volts; 120

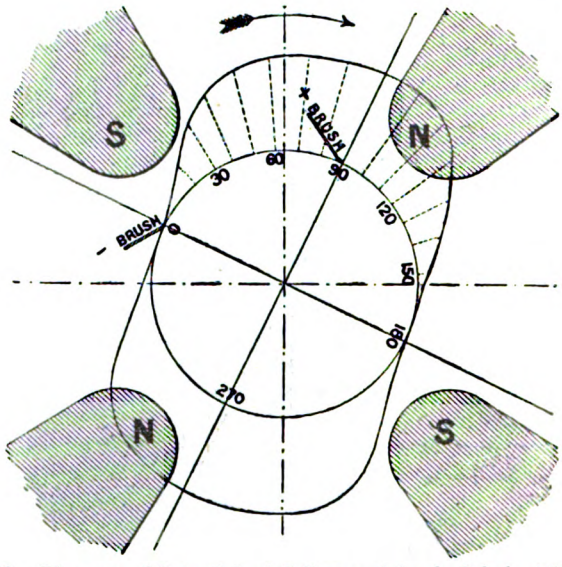

FIG. 22.—Diagrams of Potentials at Collector of 4-pole Schukert-Mordey Dynamo.

amperes, 60 volts. It will be seen that for small loads the potential drops a little; but it is under these circumstances that the engine speed usually rises slightly in practice, so that the constancy of the potential between the mains is somewhat better than the figures would show. In actual practice the regulation is marvellous. I have myself opened the circuit of a Victoria dynamo which at the time was feeding 101 lamps, 100 being at a distance, one lamp attached to the terminals of the machine. On detaching the main wire from the terminal the 100 lamps were suddenly extinguished. The solitary lamp on the machine did not even wink, and there was no flash at the brushes. The sparking was so slight it was impossible to tell whether the machine was an open circuit or whether it was doing full work. The lead was the same under all loads. There are not many dynamos that can show a result of this kind. According to measurements made by the Anglo-American Corporation's electricians, who have published the figures entire, the factor of conversion of this machine is 96·15 per cent., the electrical efficiency 85·68 per cent. These values assume the B.A. unit of resistance as the true ohm, and are therefore probably about 1½ per cent. too high. Some of these machines are wound for low speeds for ship lighting. These machines have an electrical activity slightly higher, and an efficiency slightly lower, than the high speed machines. They also have field magnet cores slightly heavier, requiring,

* Paper read before the Society of Arts, Feb. 28, 1884.

Digitized by Google

therefore, the expenditure of rather more electrical energy in maintaining the field. These remarks refer, of course, to a comparison between machines wound to light an equal number of lamps, and to work at an equal electromotive force.

A larger type of Victoria machine having eight poles, alternately north and south, set round the ring has also been constructed by the Anglo-American Corporation. This machine (Fig. 23) illuminates 750 incandescent lamps. The ring has 120 sections, there being 15 sections, therefore, between each pole and the adjacent pole of the surrounding set. As each segment of the collector is connected with those situated at 90°, 180°, and 270° distance round the set only two brushes are required.

A rather singular commentary upon the real superiority of multipolar dynamos having rings of the flattened type over the more compact ring armatures to which we have been accustomed in the ordinary Gramme machines is furnished by the announcement within the past month of a new and improved dynamo designed by M. Gramme himself, in which there is a flat ring armature rotating within a crown of 12 poles. Elaborate illustrations and a detailed description of this latest of dynamos are given in the *Revue Industrielle* of January 9th, 1884. From this article it appears that in the opinion of M. Gramme the new machine still requires some modifications to make it quite a practical machine. A glance at this drawing is quite sufficient to enable one to hazard a guess at the reasons. The pole-pieces are broad, nearly meeting one another. I should confidently predict from such a design the vice of sparking at the brushes and heating of the collector segments. Moreover, there are no fewer than 24 brushes! Think of the friction of 24 brushes, and the labour of making the complicated holders. It appears that in England we are at least a few steps ahead of France in the matter of designing dynamo machines.

Another 4-pole flat-ring dynamo has been designed by Herr Schuckert, of Nürnberg, and was exhibited at the late Vienna Exhibition. This machine, which had many excellent points in its design, was compound wound, and was calculated to give, at 450 revolutions, a current of 320 amperes at 100 volts.

The present drift toward multipolar dynamos of this type is very significant. There is little difference save in detail between the 4-pole machines of Gülcher, Schuckert, and the newer "Schuckert-Mordey" dynamo, albeit these differences are not unimportant. But all these constructors agree in adopting the flat ring. The advantage originally claimed for this construction—namely, that it allows less of the total length of wire to remain "idle" on the inner side of the ring is rather imaginary than real, for the total resistance of the armature is but a small fraction of the whole resistance of the circuit; and it is possible to spread the field so as to make all parts of the wire active without any gain whatever, if by this spreading there is no increase on the whole in the total number of lines of force in the field. The real reasons in favour of multipolar flat ring armatures appear to be the following:—First, their excellent ventilation; second, their freedom from liability to be injured by the flying out of the coils by the tangential inertia (often miscalled centrifugal force) at high speeds; third, their low resistance, due to the fact that the separate sections are cross connected either at the brushes, or in the ring itself, in parallel arc. To these may be added that, with an equal peripheral speed, the

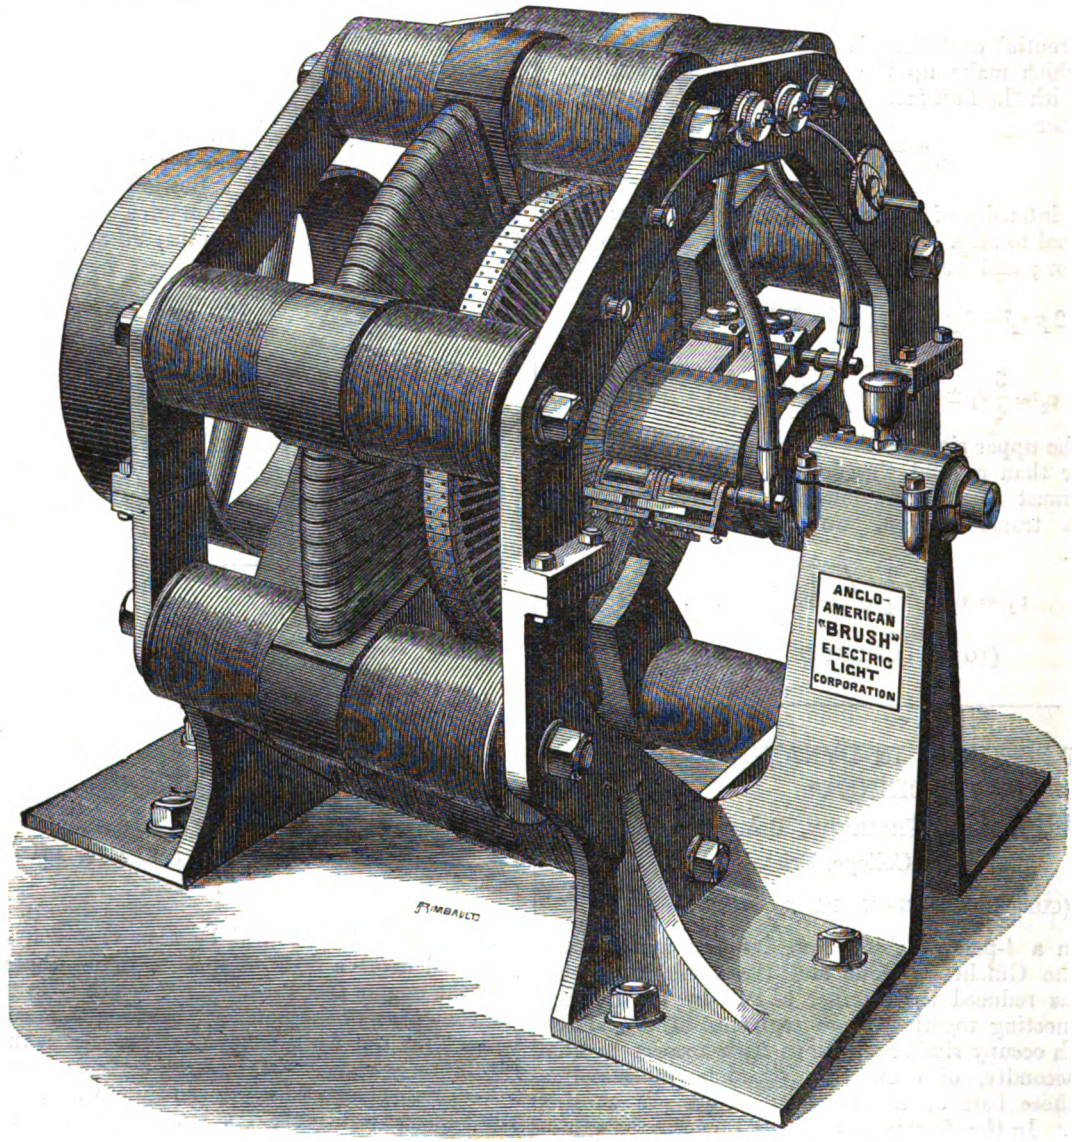

FIG. 23.—Victoria (Schukert-Mordey) Dynamo (8-pole).

Digitized by Google

armature rotating between four poles undergoes twice as much induction as when rotating between two poles, since it cuts the lines of force twice as many times in the former case as in the latter.

I pass on to the improvements made in the dynamo by Messrs. R. E. Crompton and Co. To describe the course of development which the Bürgin dynamo has undergone in Mr. Crompton's hands would alone occupy a whole evening. The armature of the original machine, as it came from Switzerland, consisted of several rings set side by side on one spindle, these rings being made of iron wire wound upon a square frame, and carrying each four coils. In this form it is described in Professor Adams's Cantor Lectures on "Electric Lighting" in 1881. Mr. Crompton changed the square form to a hexagon having six coils upon it, and increased the number of rings to ten, so that the armature consisted of sixty segments. He then found it advisable to alternate the positions of these, instead of placing them in a regular screw-order on the spindle as shown in most of the published drawings of this well-known machine. The next step was to increase the quantity of iron in the hexagonal cores, and to ascertain by experiment what was the best relative proportion of iron and copper to employ. At the same time Mr. Crompton and Mr. Kapp introduced their system of "compounding" the windings of the field-magnets. Another change in the armature followed, the rings being made much broader and fewer in number, four massive hexagonal rings, united to a 24-part collector, replacing the ten slighter rings and their 60-part collector. Quite recently Mr. Crompton and Mr. Kapp have again remodelled the style of armature, and have produced a machine which, though it is not yet quite completed, shows what may be done in the way of improvement by careful attention to the best proportions of parts and quality of material. The new dynamo weighs 22 cwts. Its field-magnets are of the very softest Swedish wrought iron, compound wound. The armature is a single ring of the elongated or cylindrical pattern, and its coils are wound upon an iron core made up of toothed discs of very thin soft iron fixed upon a central spindle, the coil being wound between the teeth as in a Pacinotti ring. In fact, the armature may be described as a kind of cross between those of Weston and Pacinotti, having also something in common with the Bürgin armature; at least, so I understand, for though I have, by the kindness of Mr. Crompton, been allowed to see the machine, I have had no opportunity as yet of examining the armature. Mr. Crompton's great aim has been to have as complete a magnetic circuit as possible, and that of the best quality. He has sought to increase the intensity of the field by having plenty of iron in the armature, and bringing that iron as close as possible into proximity with the pole-pieces by means of the projecting teeth. The result is an extraordinary increase in the "output," or, as Sir William Thomson terms it, "activity" (*i.e.*, amount of work done per second) of the machine. The machine is only 3ft. 4in. long, 12in. high, and 2ft. wide. The armature is 17in. long and 8in. diameter. At 1,000 revolutions per minute it gives 110 amperes at 145 volts, or its "activity" is 15,950 watts; but at this speed it heats too much. The power of the field-magnets is such that, at all speeds, and under all conditions of the external circuit, the intensity of the field overmasters the magnetising action of the currents in the armature coils. There is, therefore, hardly any lead at all at the brushes, and what lead there is is absolutely constant. There is no sparking at the brushes, and it is impossible to tell by looking at the brushes whether the current is off or on. Mr. Crompton is now constructing another machine of the same general design, but larger, to drive 1,000 Swan lamps. This machine, together with its engine, is only about 8ft. long, 6ft. high, 2ft. 4in. wide, and, complete with its bed plate, will weigh only about 8 tons.

It may be mentioned that in Messrs. Crompton's compound dynamos, as also in those of the Anglo-American Corporation, the series coils are wound direct upon the iron cores, and the shunt coils outside them, thus reversing the practice adopted by Messrs. Siemens and by Mr. Gülcher. It might have been expected that theory would have something to say in determining which practice is preferable. If the shunt coils of thin wire are outside, the prime cost for an equal magnetising effect will probably be greater. If the series coils are outside, the loss by heating in producing an equal magnetic effect will probably be increased. It might have been expected that, as with galvanometer coils, so with the coils of field-magnets, it would be advantageous to get as many of the turns as close as possible to the core, and, therefore, that the thinner wire should be wound on before the thicker. But, on the other hand, it is advisable to keep down the resistance of the series coils, as they will form part of the main circuit; whilst the additional resistance necessitated by winding in coils of larger diameter is not altogether a disadvantage in a shunt coil. If this proves to be the right way of regarding the problem, we shall wind the shunt coils outside those that are in series with the main circuit.

Before leaving the subject of ring-armatures I should like to refer to a form recently devised by Signor B. Cabella, which I

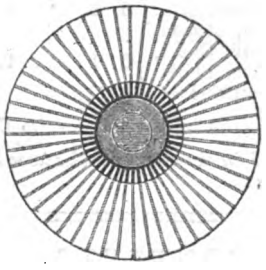

Fig. 24.—Cabella Armature.

think might be recommended to amateur constructors of dynamos as being easily made. The Figs. 24 and 25 show its general arrangements. The armature resembles that of the Edison dynamo in being built up of copper strips. These are separately cut out, and consist each of a straight piece having two arms, and projecting at right angles. A sleeve of insulating material is placed over the axle, and round this these copper pieces are arranged to the number of some 240 or so, having their arms projecting symmetrically round in two radial sets, one near one end and the other near the other. The channel formed thus between the two sets is lined with insulating material, and then entirely filled up with soft iron wire wound round. Then straight strips of copper, eight millimetres broad and two millimetres thick are screwed across the outside (like the bars of the Edison armature) from the ends of one set of radial projections to the ends of the others, forming the parallelogram section. But, in order to connect the ring all round in a con-

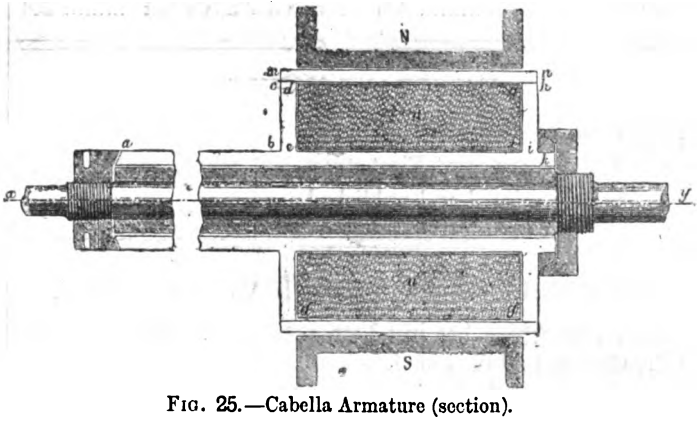

Fig. 25.—Cabella Armature (section).

tinuous circuit, these external strips of copper are connected at their two ends to pieces which project not from the same internal copper strip but from adjacent strips. Thus an external bar will connect the anterior end of the first strip with the posterior end of the second, and so on. Every third strip is carried along the axle and connected to a segment of the collector. This construction is certainly simpler than that of the Edison armature, and might be adapted to many different types of machines. According to Professer Ferrini, one of Cabella's armatures placed between the poles of a 60-light Edison ("Z," old pattern), instead of its ordinary armature, increased its power so that it could be used over 100 lamps.

## THE PROSPECTS OF TECHNICAL EDUCATION.

The report which has just been presented to the Governors of the City and Guilds of London Institute for the Advancement of Technical Education is a document of portentous dimensions, both as regards the matter it contains and the schemes with which it deals. The voluminous appendices supply an immense amount of carefully arranged and tabulated information relating to the classes, the examinations, and the general results of the technical instruction imparted throughout the country as well as in the metropolis; whilst the chairman's report, itself occupying twenty-one pages, elaborately sets forth the financial condition of the Institute. Nobody can say that the scheme was inaugurated over-modestly; the aim was ambitious, and everything was designed on a big scale; but, on the other hand, it cannot be said that, judged by results so far, the projectors erred on the side of extravagance. The fact seems to be that those who were best acquainted with the methods to be employed in obtaining large sums of money were right in deciding to start boldly with a large sphere of operations. Many causes, some of them no doubt political, may have combined to induce the various City Guilds and Livery Companies to evince a sudden interest in technical instruction, and to prove it by a liberality which was truly magnificent. Evidently the time was ripe for an appeal of this sort, and in the peculiar circumstances no difficulties were experienced in convincing the parties that a great deal of good would come of making technical instruction more general, and that the City Companies would profit somewhat by identifying themselves with the movement. From the report before us we should be inclined to say that they have no reason to be dissatisfied with the investment, the munificence with which the scheme has been patronised and the work it has already achieved being sufficient to mollify even a President of the Board of Trade, which is saying a great deal.

The financial aspect of this question is indeed its most striking feature; for although the results, compared with the expenditure, must at first be very small indeed, the present outlay is a tolerably certain criterion of what will be accomplished in the long run. It is essentially a scheme the fruits of which cannot be ripened and gathered until many years have elapsed. Giving technical knowledge is one thing; to see it reflected in the manufacture and art products of the country is another and later operation for which we must be content to wait. But though the process was to be slow the originators of the scheme decided it should be begun on a broad and liberal basis; and in point of fact, we have now or very soon shall have, an organisation fully equipped and endowed, which, under less favourable conditions, it would have taken many generations to have built up. In London alone there is already an institution which expends annually a sum of over £16,000 either on itself or in aid of affiliated institutions; and there is in progress of building another institution, the expenses of which will probably soon be as large, or even larger. The income from the pupils, it need hardly be said, covers but a very small portion of this expenditure, the remainder falling entirely upon the endowments. But these constitute only a fraction of the sums actually expended since the Cowper-street School was taken in hand. That school has expanded into the Finsbury College, which again has given rise to the South London School of Technical Art, and the crowning edifice of the Central Institution at Kensington, now nearly completed. On the last-named building more than £60,000 has already been spent, and on the Finsbury College £33,000, the total cost of its equipment when completed being estimated at £35,000 or thereabouts. The School of Technical Art has only absorbed the very modest sum of £2,330; but this we may hope does not represent the total expenditure on art training. Indeed we observe that the Cowper-street School Rooms, now vacated for the more commodious premises of the college in Finsbury, are now used for the Department of Applied Art—whatever that may mean.

We have said that some sixty thousand pounds have been expended in the erection of the Central Institution, Exhibition-road, which is expected to be handed over by the contractors in the course of a few weeks. To furnish this building and to provide it with the necessary apparatus another £20,000 at least will be required. There are no funds in hand; but an appeal is urgently made, and made, too, in such a way as to betray little fear but that it will be promptly responded to. Unless the enthusiasm for technical instruction has abated under the chill of political apprehension there is no doubt that the purses which have so freely opened on former occasions will open again to this fresh de-

Digitized by Google

mand. For the efficient working of the Central Institution when properly furnished the annual sum of £15,000 will be required. This estimate, as we have already hinted, is a very low one; and for some time to come the fees cannot be expected to contribute more than £2,000; later on they may reach £5,000, leaving a permanent charge upon the funds of the Institute of £10,000 per annum. This, however, is the sum originally contemplated when the Central Institution was projected, so that we may assume that practically it has been endowed to this extent under the permanent contributions from the various companies. What the annual estimated income from these sources may be we cannot precisely gather; but some idea of its extent may be gathered from the balance-sheet for 1883, which shows subscriptions either actually collected or due amounting to £23,470, exclusive of £11,271 under the heading of donations to the building fund. At this rate there is not the slightest cause for apprehension on the score of income, and the fact reflects the highest credit on the generosity, wisdom, and public spirit of the City Companies.

We have dwelt at this length on the financial position of the Institute because it is thus made evident that its future career and reputation will depend solely upon the work it performs, and will not be trammelled or impaired for lack of means. Already it is doing good service in having encouraged the creation of similar schools in the provinces, and the endowments of scholarships by private hands. Indirectly, too, it is encouraging the system of apprenticeship—a system which, whether promoted best by reduced fees or not, ought to be studiously fostered by the advocates of technical education. With the general working of the scheme we have at present little to say. It is gratifying to notice, however, that the supply of qualified teachers, which at one time gave rise to some uneasiness, has been improving of late, notwithstanding the higher qualifications, especially of a practical kind, now required before registration. In a former article we commented upon the inexpediency of combining the office of teacher and examiner in one person. At the forthcoming examinations, which are advertised for next month, we trust that this error will be avoided.

## CORRESPONDENCE.

### PRINCE LEOPOLD AND THE POST OFFICE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: "On the way of wisdom and virtue we shall all advance the farthest if we all advance in common." "Such," said Dr. Adler in his discourse on Saturday, "was one of the last utterances of Prince Leopold." Dr. Vaughan, in his sermon at the Temple the day following, in referring to the death of the Prince, said, "We trust he has found a home and a solace in the companionship of just men made perfect;" and the Bishop of Peterborough, preaching at the same time at the Chapel Royal, fearlessly told his aristocratic hearers that "England was poorer for this death—for the end of a life that was true and honest, and that set a lofty example in high places." It will do the readers of *The Electrician* no harm if in giving these extracts I am only reiterating a common sentiment. But I would go a step further, and give an interesting fact in support of these sentiments. Prince Leopold gave himself the trouble to understand the grounds of my contention with the Post Office, that although by the constitution "the Sovereign could do no wrong," it was impossible, without risk to the constitution, that the prerogative of the Sovereign should be delegated to the unrestricted exercise of any of Her Majesty's public departments, the remedy against abuse in such departments being by petition to Her Majesty, and such petitions not being subject to the control or consideration of Parliament. Mr. Collins, however, could at length only write, "The utmost that H.R.H. Prince Leopold can with propriety do to assist you in bringing your petition before Her Majesty is to forward your letter to his Royal Highness to Her Majesty's Private Secretary." I believe this was all that the Prince could do, and I also believe that it was effective in insuring the utmost that Her Majesty could do. Her Private Secretary wrote to me as follows:—"Sir: In reply to your letter, and also to one forwarded to me, which you addressed to Prince Leopold, I am desired to say that the Queen entirely refers the subject of your petition to Lord John Manners, and Her Majesty cannot enter into any further discussion of the subject." From that time to the present nothing whatever has been done in the matter by Lord John Manners or by any one else deputed to represent him. Scandals of this kind are not infrequent, it is said. Be it so—this does not lighten my grievance, or give one compensation for the breach of faith, resulting in heavy loss. Prince Leopold was conscious of this alarming departmental anomaly, and had his life been spared he would certainly have frowned it down.—Yours, &c.,

RICHARD HERRING.

27, St. Mary's-road, Canonbury.

### OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to your correspondent, "Mos Legem Regit," I wish him to distinctly understand that I am not writing at the "instigation" of any of the telephone companies.

He evidently does not know the various circumstances in which "induction" is so troublesome. I have only to state (what is really a most obvious fact, known to any one having even only a slight practical knowledge of telephony) that where two wires are laid close together a current travelling through one of them will inevitably produce a current and a reproduction of the speech through the other (a fact which your correspondent will not require to make a very deep research to ascertain), and I feel sure he will not require to further prolong this correspondence.

I refrain from noticing any other portions of his letter as being the mere quibbles of a "special pleader."—Yours, &c.,

TELEPHONIST.

### EARTH CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Last November I prepared an article and diagrams of the observations of earth currents taken here during the preceeding month for your paper. But for a little trepidation on my part, this would already have been in your hands; now, however, that Mr. Blavier, in the *Journal Télégraphique*, has ventilated the subject in a manner somewhat analogous to mine, I feel induced to forward you my paper, trusting that it will be acceptable, and to a certain extent help on the subject a step further towards solution.

In looking over the list of works and articles compiled on earth currents in your appendix of September 22 last, one fails to find any satisfactory or any exhaustively conclusive result of the researches which may have been made from time to time to determine the origin of earth currents in general, and whether such currents, in the sense implied, do or do not exist, at least in submarine cables.

It is certainly to be regretted that, invariably, the electrician's duties are so manifold that he has either no time, or else he is so overworked, that he has to forego all taste for experimenting upon the purely problematical, which, however, everybody to-day is so anxious to determine and define.

As I have on previous occasions brought before your readers various statements of electrical disturbances passing through cables with reference to earthquakes, I have lately taken a series of readings on three of the principal cables radiating from this island, over which, during the so-called seismic

Digitized by Google

month, I had anticipated many telluric phenomena to be measured and defined.

The three charts show the maximum and minimum readings

OTRANTO CABLE.

Take the chart of the Otranto cable, the further end of which was joined to a copper earth, there being a land line of three miles between the hut and the station. The deflections *from* the cable were invariably positive under whatever condition of wind or weather, and they were very steady and too weak to ever affect our working. In this case the difference of potential between the two points may be clearly traced to the weak voltaic cell set up by the copper-plate earth at that end and the iron earth at this, and also to the chemical nature, or rather the difference in the electrolysis surrounding the respective earths, for it will also be observed that when "cable" earth was put on at the Otranto hut a precisely proportionate positive deflection was obtained, although now the "earths" were identical.

That earth currents, so called, are influenced by some kinds of atmospherical electricity seems undoubted, unless the inflections of the chart readings are due to more or less decomposition of a thinner or denser charged fluid round the earth terminals, and they may also be due to the friction of moving masses of water.

The maximum deflection for the month was during a violent gale from the N.E., the lowest readings were always during a thunderstorm; thus it would seem that during an atmospherical electric discharge, although the cable, at whatever depth it may be laid, shows by a "kick" the discharge to earth passing

CORFU CABLE.

around it, the actual earth current is *nil*. It is therefore demonstrated that however much cables may feel the effects of aurora or other magnetic storms through the insulator of dry cold air by violent oscillations, the presence and discharge of lightning renders them perfectly quiescent.

In support of my theory that earth currents are not atmospherical, I took a series of readings over my subterranean cables, 300 yards in length, using the same cable earth at both ends, and I obtained a deflection equal to 35,000 degrees of the scale. To what was this deflection due? Clearly not to any atmospherical disturbance, because such a small length could not be subject to it, and it can only be traced to the different electrolysis of each end, for when a copper earth was used instead, at one end, there was little or no difference in the results obtained, and no extraneous cause can be found, for the insulation of the cables is perfect.

On referring to the chart of the Corfu cable, running in the same direction as the Otranto one, at which end the same earth is used as at Zante, it will be seen that the greatest deflection was in very dull dirty weather; during a thunderstorm or calm weather the section was comparatively free. On the 17th of the month, after taking my readings, the clerk

Digitized by Google

told me that a very slight shock of earthquake had been felt that morning, and as your readers will observe from the chart, the readings fully corroborate some of my former statements, showing the magnetic increase during or subsequent to a shock, the oscillations on that day during a two minute reading being from a maximum equal to 12,000 degrees *positive* to 15,000 degrees *negative*, and it is worthy of note that no other shocks took place over any of these sections during the month, as a reference to the chart will show. It was on this day that I observed that, when Corfu was to a copper earth through his relay of 800 ohms resistance, the deflections were all plus 20,000 degrees. Thus on the day mentioned 15,000 degrees negative, when to earth on the cable, turned to 5,000 positive, and the 12,000 positive rose to 32,000 when through his instrument. Now, when Otranto was to earth (copper) through his instrument, of 800 odd ohms resistance, the chart deflections fell nearly one half, whilst on Candia, who, like Corfu, gave iron earth, the deflections were increased (positively always) 25,000 deflections when through the instrument to a copper earth.

To my mind these results open up a vast field for more minute observations, as it is evident if on the Corfu cable, with the same earth at each end, a negative deflection of 20,000 degrees exists, we shall have a dead zero when through the instrument, and this result I actually did get, and refer to later on.

Taking now the chart of the Candia cable, it is rather strange that the first three days should have given almost the same results as those obtained from the other two cables running in an opposite direction.

The readings, whether positive or negative, were invariably steady, and although on the 17th, during the earthquakes at Tchesmé, the deflection sprung up from a low negative to a very high positive, there was nothing erratic or magnetic in them, clearly showing Candia and its cables were outside the radius of superficial seismic force.

On this day the iron earth gave 65,000 degrees, and when the instrument was put on it was 90,000, and on the 26th, when the readings were negative, the iron gave 30,000, the copper 5,000. On the 28th this cable when earthed gave 0, 50, and then 800 negative, rising to 5,000 negative steady. As soon as the instrument was joined up I got an exact deflection of 20,000 positive. The other day, previous to the sharp shock of earthquake at Patras, during my testing of the Candia section, the earth current was for five minutes absolutely *nil*, then it oscillated between a maximum of 5,000 positive and 8,000 negative, the light passing gradually over the scale from side to side perfectly magnetic. It eventually fell nearly to zero.

In conclusion, I think we may justifiably say that whatever influence atmospherical disturbances may bring to aerial lines, it seems certain from these results that they in no way affect submarine cables, and the phenomena may possibly by continuous research be traced to causes we can suspect and imagine, but can hardly define.—Yours, &c., W. G. FORSTER.

February 6th, 1884.

## MANCE'S METHOD.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to Mr. Hillyer's concluding remark in his letter of last week, I think the difficulty which arises in consequence of the change in the intensity of the current passing through the battery may be reduced to an amount practically inappreciable.

In the new edition of the "Cours de Physique," par MM. Jamin and Bouty, Vol. 1., p. 92, the current through the battery is given

$$I = \frac{V}{D+A}\left[1 - \frac{BE}{B(D+A+E)+EA} + \frac{A^2}{A(D+C+F)+FD}\right].$$

From this it appears that when the connection between Q and P is broken and F becomes infinite the last term disappears, while the other terms remain as before.

The change produced in I is therefore

$$\frac{V}{D+A} \cdot \frac{A^2}{A(D+C+F)+FD} = \Delta I,$$

while the current through the branch Q P is

$$f = \frac{VA}{A(D+C+F)+FD},$$

whence

$$\Delta I = f\frac{A}{D+A}.$$

Hence, if we make A very small in comparison of D, we reduce $\Delta$ I to a very small fraction of $f$.

If, as usual, we may treat F as nothing, then

$$J = \frac{V}{D+C};$$

$$\Delta I = \frac{V}{D+C}\,\frac{A}{D+A}.$$

$$\text{The current in } B = \frac{fF - eA}{A+B},$$

and when F = 0, this current becomes

$$-\frac{eA}{A+B} = -\frac{eD}{D+C},$$

the – sign showing that the current runs from 0 to Q.

This is in fact the case represented in Mr. Hillyer's Fig. 3.

This suggestion seems to me to entirely remove the objection raised to Mance's method by Dr. Oliver Lodge, and quoted by your correspondent; but I should be glad to hear more on this point.—Yours, &c., W. M. MOORSOM.

## LITERATURE.

*Dictionnaire d'Électricité et de Magnétisme, Étymologique, Historique, Théorique, Technique, avec la Synonymie, Française, Allemande, and Anglaise.* Par ERNEST JAQUEZ. [Paris: Librairie, C. Klingksieck, 11, Rue de Lille. 1883.]

Some of our readers may remember that during the interval which elapsed between the first and second series of *The Electrician* several volumes were issued of a semi-electrical paper called the *Electric Telegraph and Railway Review*. In this paper Mr. Desmond G. FitzGerald commenced a "Dictionary of Electrical Terms." The part of this dictionary that was published engenders regret that it was never completed. We know of no other attempt to issue such a dictionary till the issue of the one before us. The first dictionary upon any technical subject can hardly be expected to be complete, and the best course to pursue is to welcome its introduction, assist in its circulation, and suggest that those who use it should favour the author with their criticisms. A second edition would thus gain in value, and gradually the work would obtain the completeness of reference it should have. Let us take any page at random. The book is open at page 70, and the first word is "Duplex." The credit of solving the question of duplex work is given to Gintl in 1854, and the names of MM. Preece and Stearns are also mentioned. We would add to these names, and especially would we add the names of those who succeeded in duplexing long cables. A little lower down the page we come to "Dynamo-électrique." Here there is no mention of Faraday, and while Gramme is named, Pacinotti is not mentioned, and so on.

It must not be understood that the author is at all chary in mentioning names or authorities. Far otherwise, he is constant in referring to his authorities, and we mention the matter more to show that one person, however able, however anxious to give the best, must of necessity have weak points. These weak points can be remedied with the aid of others. The value of a dictionary depends upon exactness of definition, fulness of historic reference, correctness of dates, and completeness of words. For a first attempt M. Jacquez has produced a good work—good enough, in fact, to make us anxious for a better edition.

# ON A NEW STANDARD OF ILLUMINATION AND THE MEASUREMENT OF LIGHT.*

By WILLIAM HENRY PREECE, F.R.S.

1. The present position of photometry as practically applied to electric lighting is by no means in a satisfactory condition. Mathematical accuracy in the measurement of the intensity of the light emitted by a given source is unobtainable owing to the numerous disturbing influences of quality and quantity which render impossible any graduated scale of light. An *absolute* standard of light has not yet been obtained. I have long felt that to meet the case of electric light illumination we must not depend upon any direct comparison between the light emitted by the source to be measured and any given recognised standard of light; but that we should rather make our standard of comparison an area illuminated to a given intensity whatever be the source of light. We do not want to know so much the intensity of the light emitted by a lamp as the intensity of illumination of the surface of the book we are reading, or of the paper on which we are writing, or of the walls upon which we hang our pictures, or of the surface of the streets and of the pavements upon which the busy traffic of cities circulates. Illumination of this character depends not on one source only, but on many sources of light distributed in innumerable ways. Hence, I propose to measure the illumination of surfaces quite independent of the sources of light by which they are illuminated. The difficulties in comparing the illumination of spaces have hitherto been insurmountable, but now, thanks to the beautiful little glow lamps introduced by Mr. Swan, these difficulties have disappeared.

The standard I propose is the space illuminated by one British standard candle at 12·7in. distance, which is the same as the illumination given by one French standard "bec" on the same space at one metre distance.

2. The principle of measurement which guides us in nearly all the methods at present in practical use is to compare two surfaces equally illuminated to the same intensity by lights placed at different distances, and to compare them by the law of inverse squares determined by Kepler. This law, however, assumes a clear space through which the light is transmitted, and the emission of this light from a point. Distance, therefore, becomes essential, and the error introduced by large flames or by the diffusion of light becomes difficult to eliminate; indeed, by the present system it is well nigh impossible to measure satisfactorily the light-giving power of several lamps distributed over a room or large area. Moreover, the principle ignores the presence of different colours, and it involves the necessity, with electric arc lamps, of taking measurements at different angles.

Up to the present time, the simplest and perhaps the most favourite mode of measurement is Rumford's plan of contrasting shadows, but Bouguer's method of comparing equally illuminated surfaces, as carried out by Ritchie and Bunsen, is also in great favour.

3. All these plans, however, are dependent upon the establishment of a uniform standard of light. Although in England Parliament has legalised the standard candle, it has been found so inconvenient in practice, owing to its want of uniformity, that Mr. Vernon Harcourt has felt it advisable to replace the standard spermaceti candle with a flame resulting from the combustion of pentane. In France, again, the standard is the Carcel bec, burning at the rate of 0·0042 kilo. of pure colza oil per hour, with a flame of 40 milllims.; while Draper (1847), Zöllner (1859), and Schwendler (1879) proposed a given length or surface of platinum raised to incandescence by a current of electricity as a useful standard. At the Congress held in Paris last year it was suggested that a convenient standard would be the light emitted by a square centimetre of incandescent platinum maintained at its fusing point, but up to the present moment no one seems to have devised what really may be called an absolute standard of white light. The question is now being considered by a committee of the British Association. If it were possible to find a convenient, simple, fixed, and uniform material which, having a resistance of 1 ohm, could be raised to incandescnce by 1 ampere flowing through it, we should have a convenient standard; but this has not yet been obtained.

As I have said, the standard of comparison I propose is a uniformly illuminated surface. I thought at one time that we might have made use of sunlight for this purpose, but I find that sunlight and moonlight are even more variable than the light produced by artificial means, and, after innumerable trials, I have come to the conclusion that the standard which I have proposed is one very easily obtained, and though not absolutely fixed, can be made as nearly uniform and reproducible as any standard hitherto suggested. It is true that it is of a secondary character, and dependent primarily upon a recognised standard source of light; but this primary standard remains in the laboratory, while the measurement can be made in the streets, on board ship, or wherever the surface of illumination may be.

4. Having thus fixed upon a standard of illumination, it became desirable to devise an instrument that would enable us to compare areas differently illuminated.

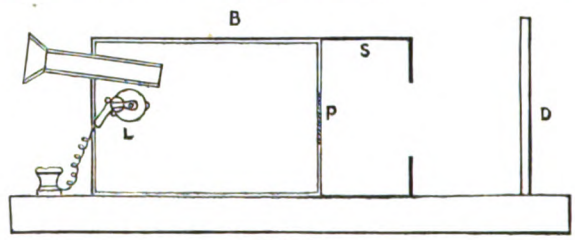

FIG. 1.

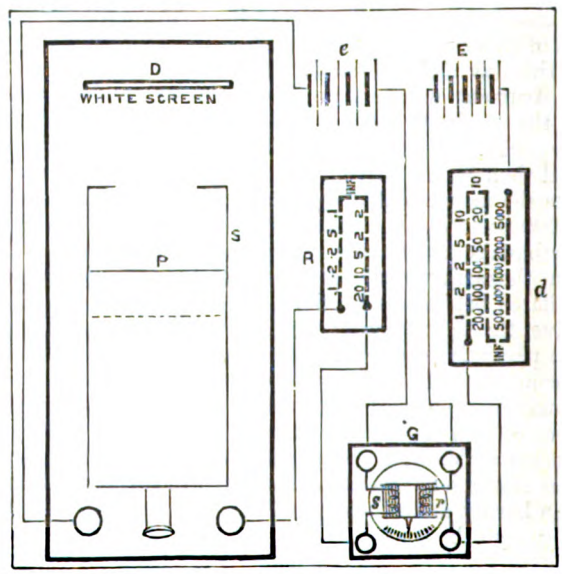

FIG. 2.

For this purpose I make use of a small Swan glow lamp giving 2½ candle-power with the current produced by 5 volts. The construction of the photometer is shown by Figs. 1 and 2. The lamp (L) is fixed inside a cylinder or box (B) blackened in the interior, over the end of which is stretched a diaphragm of drawing paper (P); the latter has a round grease spot in the centre about the size of a shilling, as in Bunsen's photometer. At about 12in. distant from the end of the tube a screen (D) of white drawing paper is fixed. The diaphragm (P) is so screened by a sliding cover that no light falls upon it but that which is reflected from the drawing paper (D). At the end of the tube where the glow lamp L is set is an eyepiece, through which the illuminated surface of the diaphragm at the end of the tube can be observed. Beneath the base of the instrument is fixed a secondary battery (*e*, Fig. 2) which enables us to transmit a current of any desired strength through the glow lamp (L). A rheostat (R) is fixed in circuit with this battery, and enables the current to be adjusted at will; the strength of the latter is read on a graduated electro-dynamometer, or upon a galvanometer.

* From a paper read before the Royal Society, June 21, 1883.

Digitized by Google

For laboratory purposes a more accurate mode of measuring the intensity of the current is the following :—*

G is a galvanometer wound with two coils, one ($s$) consisting of a short length of thick wire, and the other ($r$) of a long length of thin wire. In circuit with the latter coil is a resistance, $p$, and a standard battery, E.

The relative deflective values of the coils $s$ and $r$ for similar currents being as 1 to $n$, then when balance is obtained on the galvanometer the current C flowing through the coil $s$ will be—

$$C = \frac{nE}{r+p},$$

$r$ being the resistance of the galvanometer coil and battery, and E the E.M.F. of the battery E.

Thus if the relative deflective values of the coils $s$ and $r$ are as 1 to 473, that is, if $n = 473$, then if E consist, say, of a 5-cell Daniell battery, and the resistance ($r$) of the galvanometer coil and battery be 800 ohms, the current C, when balance is obtained by adjustment of $p$, will be

$$C = \frac{473 \times 5 \times 1{\cdot}07}{800+p} = \frac{2530}{800+p}.$$

Practically with this arrangement a change of $\frac{1}{1000}$th of an ampere in the current through the coil $s$ can easily be detected, and currents can be read to three places of decimals.

To work the instrument it is only necessary to place the screen (D) in the place whose illumination is to be determined, and then by means of the rheostat (R) to lower or increase the current passing through the lamp until the grease spot, when viewed through the eyepiece, becomes invisible, then the light reflected on the diaphragm and transmitted through the grease spot by the distant surface of drawing paper will be equal to the light thrown upon the opposite side of the diaphragm by the glow lamp. The current producing the light thus becomes a measure of the illumination of the screen.

The following measurements were made to determine the current that gave various degrees of illumination—the source of light being a standard candle.

| Distance of source of light from illuminated surface. | Equivalent degree of illumination. | Current through lamp required to produce balance of illumination. (C.) | $C^6 \times 15{\cdot}994$. |
|---|---|---|---|
| Feet. | | Amperes. | |
| ·50 | 64·000 | 1·260 | 64·000 |
| ·75 | 28·445 | 1·100 | 28·335 |
| 1·00 | 16·000 | ·959 | 12·442 |
| 2·00 | 4·000 | ·790 | 3·888 |
| 3·00 | 1·778 | ·690 | 1·726 |
| 4·00 | 1·000 | ·651 | 1·217 |

From these experiments it appears that the illuminating power of the glow lamp increases in the ratio of the sixth power of the current. Hence it is only necessary to read the current that gives the necessary equivalent to determine the degree of illumination.

The current in amperes thus gives, for the particular glow lamp employed, a number whose sixth power expresses the amount of the illumination measured.

The apparatus works with ease and regularity, but it has this difficulty—that it is dependent upon the constancy of the lamp, a point not yet absolutely attained. The glass envelope of the lamp becomes deadened by use ; the carbon fibre of the lamp gradually becomes deteriorated ; and the vacuum sometimes fails. These operations, however, are very slow ones, and it is only necessary occasionally to compare either the light given by unit current with that in the laboratory thrown upon a surface by a standard candle or by one of Mr. Vernon Harcourt's pentane lamps.

It is, however, certain from numerous experiments and practical trials that the light produced by the incandescence of a given carbon filament due to the passage of a given current is more easily reproduced from one time to another, and is more uniform than probably any other artificial standard of light.

* Cardew, *Proceedings* of Telegraph Engineers and Electricians, Vol. II., p. 301.

## DESCRIPTION OF THE ELECTRICAL LAUNCH BUILT LAST YEAR.*

By A. F. YARROW, Esq., Member.

The object of the present paper is to briefly describe an electric launch built last year jointly by the Electric Storage Company, Messrs. Siemens Bros., and ourselves. After numerous trials had taken place with it on the Thames, it was forwarded to Vienna, where it was shown at work on the Danube during the Electrical Exhibition.

I do not propose to trace what has previously been done in this direction, that having been already fully dealt with by others, more particularly of late by my friend, Mr. Reckenzaun, in communications to the British Association and to the Society of Arts ; to these papers I would refer those gentlemen who are interested in this subject, treated more particularly from an electrical point of view.

The launch in question was propelled by a current obtained from storage cells or accumulators, and not from a primary battery. With a primary battery the electricity is generated direct by chemical action, but in the case of the accumulators they have to be first charged ; in fact, the electricity has to be pumped into them, as it were, at intervals of time, to be given off afterwards when required. From this it is clear that if a primary battery could be introduced suitable for the propulsion of launches, it would possess an evident advantage, by avoiding the difficulties and delays incidental to the charging process ; such a battery, I believe, remains yet to be discovered.

The accumulators adopted in the present case consisted of a number of storage cells, known after the names of the inventors, being of the Faure-Sellon-Volckmar type, a drawing of which is shown on the wall and a sample on the table.

They may be briefly described as follows :—Each cell measures 9½in. long by 9in. wide by 7½in. deep ; the cell itself can be of glass, porcelain, or of any material not attacked by acid. Into each of these are placed eighteen pairs of plates, and I would now beg your reference to the plates shown on the wall. The positive plates are pasted with red lead, and the negative plates are pasted with litharge. They are first subjected to the process of "forming"—that is to say, by means of an electric current the red lead becomes peroxide of lead—a substance of a chocolate colour—the litharge of the negative plate is reduced, and becomes spongy lead. The plates are immersed in the cells previously referred to, containing diluted sulphuric acid in the proportion of one of acid to four of water. The lead casting or grid is shown above, the others serve as a conductor to the electric current. It has numerous square dove-tailed holes, which are filled or pasted with the oxides of lead above mentioned, and it is by these oxides that the chemical or electrical energy is evolved. These dove-tailed holes serve as a convenient means of keeping the red lead and litharge in close electrical contact.

The first thing is to charge the cells. This is done by means of a machine capable of generating electricity, usually termed a dynamo. It is driven by a steam engine or otherwise, the power required to give motion to it being absorbed in overcoming the resistances due to the production of the electric current and to the friction of the machine itself. The ends of the wires of the dynamo are connected to the accumulators, and on the armature being made to revolve, a current of electricity is produced. When the accumulators are in this manner fully charged, they are ready at any moment for use ; that is to say, whenever the ends of the accumulator are connected by means of a wire or any conductor of electricity, a current is given off, which is capable of driving an electro-motor, thereby producing power.

The effect of charging the cells is to cause chemical action, the positive plates combine with oxygen, and the negative plates take up hydrogen. On giving off electricity the reverse action results—the positive plates give up oxygen, and the negative plates give up hydrogen, leaving everything in the exact state it was prior to the charging process, the chemical change in the one case being the result of the power expended, and in the other, the power generated being the result of the chemical change.

The losses incurred in the process of charging and giving off electricity are estimated differently by various authorities. An average of these estimates gives approximately the following :—

| | Per cent. | Residue per cent. |
|---|---|---|
| Starting with the engine which drives the dynamo, converting mechanical energy into electric energy, there is a loss of ..... | 15 | 85 |
| Loss in passing the electricity into the accumulators | 10 | 76½ |
| Loss due to the reverse action, namely, converting stored electricity into mechanical energy..... | 25 | 57½ |

Leaving an estimated residue of 57½ per cent., putting aside the

Digitized by Google

sub-division of the losses. From our own experience I am satisfied that, from the power required to charge the cells at our works, compared with the ultimate power given off to drive the launch under ordinary working conditions, a return of from 45 to 50 per cent. may certainly be relied on.

The diagrams on the wall show at a glance the general arrangement of the launch ; sixty-five storage cells were placed below the floor, and sixteen under the seats, eight on each side.

The motor made by Messrs. Siemens Bros. they state to be capable of working up to 8 to 9 horse-power tested on the brake, but in the launch it probably did not exceed 7 horse-power. It will be seen to have been placed near the stern, and coupled up direct on to the screw-shaft.

| | Tons. | Cwts. |
|---|---|---|
| The weight of the hull was | 2 | 0 |
| The weight of the storage cells | 2 | 0½ |
| The weight of the dynamo, shafting, stern tube, and propeller | 0 | 10 |
| Making a total displacement of | 4 | 10½ |

The dimensions were 40ft. in length by 6ft. beam.

It will be seen that, owing to the very low position of the accumulators, a narrower beam in proportion to length is admissible than in a steam launch, assuming an equal stability in both cases, and any reduced resistance due to the finer lines may fairly go down to the credit of the electrical system.

On a continuous run it was found that as the accumulators became weakened the speed gradually fell off. During the first three hours this reduction amounted to about half a knot per hour. To meet this difficulty, when a continuous run was required at a uniform speed, a certain number of cells, say fifty or sixty for example, were connected up, the current from these only driving the motor at first, and as it fell off other cells were coupled up and brought into the circuit, so that the additional fully-charged cells make up for the deficiency of those partially exhausted. In this manner the boat could be kept running for five to six hours.

If, however, the best result was required for a short time only, all the cells were connected up, and the full power used.

A small switch-handle placed close to the steersman enabled him to put in and out of circuit any number of cells, depending upon the speed required and the amount of charge still remaining.

The best result obtained at Long Reach, with six persons on board, and a displacement of about five tons, having seventy-one cells in circuit, was 6·9 knots, *i.e.*, eight statute miles, the revolutions of the motor being 674 per minute. Each cell, when fully charged, weighing ½ cwt., is stated to be equivalent to one net horse-power for an hour developed on the shaft, but I believe, in actual practice, a considerable reduction from this estimate must be made. No doubt, had the motor been designed with the view to make a less number of revolutions, greater efficiency would have been obtained from the propeller, which was 24in. diam. by 13in. pitch.

There exists a great variety of electro-motors ; the main feature, common to all, however, is that two or more electro-magnets are so arranged that they alternately attract and repel one another, the current round the one set of magnets being continually reversed by self-acting mechanism.

Comparing this electrical-launch with a steam launch provided with an ordinary high-pressure engine, giving the steam launch an increased beam, in order to secure the same stability, making engine, boiler, water in boiler, and coals sufficient for a six hours' run equal in weight to the accumulator and motor, the mean speed of the steam-launch would have been from 1½ to 2 miles an hour faster than the electrical-launch. Had it been for use in salt water, necessitating a supply of fresh water as well as fuel to be carried for the six hours, the above advantages in favour of steam would be much reduced.

The steersman was provided with a reversing lever, by which means he could change the direction of the current and reverse the motor, and it was found from actual practice that the entire management of the launch was quite within the easy control of one man ; he was also provided with indicators showing the quantity and intensity of the current passing, and approximately the amount of charge remaining in the accumulators.

The floor of the boat, as will be seen, rests upon cross-pieces, and is easily removable, being so arranged that the water-tight trays containing the various sets of cells could be readily lifted if required, but this was found rarely necessary.

More cells could be fitted to the boat, giving either a higher speed or a longer duration of run, and this greater number could be added with advantage, so far as might be consistent with the size of the boat and the duties she would have to perform.

Touching the time occupied in charging the accumulators, this depends upon the amount of current generated in the first instance. Assuming the least waste or loss of energy is desired, the time for the charging process should occupy about 25 per cent. longer than the giving-off process, *i.e*, if the boat is to run for six hours the charging should be estimated to occupy seven and a half hours. It can be done faster, but with a greater loss of power.

The leakage of electricity when standing depends to a great extent upon the perfection of the insulation ; this loss has been estimated by different authorities at from 2 per cent. to 10 per cent. per day. We ourselves took no steps to test this, but I can say that if the accumulators were charged on a certain day, the boat would be available for use any time during the following week.

It will be seen that as it is ready for use at any moment, consequently in this respect it should be compared with a steam launch having steam always up. In the one case, however, a man must be in constant attendance, while in the other this is unnecessary.

The difficulties that we met with while the launch was in our hands were not so great as we expected, and were in a great measure due to want of experience on our part ; this was especially the case as regards insulation, sufficient care not having been taken in the first instance. The motor gave some trouble, probably due to passing excessive currents through it with a view to obtain the best possible speed, and after a run of half an hour or so on two occasions the machine became over-heated, the insulating covering of the wires being damaged.

These difficulties, on better acquaintance with the subject, would doubtless vanish.

It would be well to remark that the current adopted was such as not to be in the least degree dangerous to life.

The Board of Trade limit of intensity to be perfectly safe is 200 volts, while the maximum intensity of the current which could be developed on board the launch did not exceed 120 volts.

As to the cost of working, I will abstain from any attempt at giving figures, which, at the present stage of development of the subject, would be unreliable.

Touching the durability of the accumulators, we have no experience ourselves, but I believe, when in the hands of those who thoroughly understand them, the wear and tear is by no means excessive or prohibitory.

They may be spoilt in a few minutes by neglect or inexperience. The same, however, can be said of a steam boiler.

As to the durability of the motor, the wear and tear of this would, I believe, be small, although the strains are considerable ; there is no change from a reciprocating to a rotary motion necessary, and every part of the machine is capable of being balanced with great accuracy.

As to the direction in which to look for improvements, not being an electrician, I am unable to suggest, but what is evident at a glance is that both dynamos, as well as accumulators, find a sale mostly for electric light purposes, in which case they are stationary, and weight is no object. I believe in the direction of a reduction of weight something at least might be secured to improve this system as applicable to propulsion. At present the limit of power which a motor is capable of developing is partly determined by the heat produced by the current in passing through the wires, and the risk of destruction of the insulating material surrounding these wires, which is usually cotton or silk. It has been suggested to substitute for these asbestos or some non-conductor capable of withstanding a high temperature. If this is practicable a more powerful current could be employed, and a greater power developed from a given weight of machine.

Comparing the electrical system with steam, the advantages in favour of the former may be stated briefly as follows :—

(1) Entire absence of noise.

(2) Great cleanliness.

(3) The whole of the boat is available for passenger accommodation, the midship or best part of it not being occupied by machinery.

(4) When once charged it is ready for use at a moment's notice.

The points against it are :—

(1) Difficulty and delay in frequent charging.

(2) Greater first cost.

(3) Greater cost of working in those cases where an engine has specially to be laid down for the purpose of charging.

Probably the first cost of the accumulators may be ultimately materially reduced, there being a very large difference between their present price and their cost of production.

Under those circumstances, where the above objections exist to a minimum and the advantages to a maximum extent, the electrical system, even at its present stage of development, seems to me to be quite available ; for example, when a natural source of power exists, such as a fall of water, a dynamo may be easily driven, and at a nominal cost, to charge the cells. If wished, this could be done during the night, and the boat would be available for use during the day. Under such conditions the electrical system would, I believe, have a balance of advantages in its favour.

It is reasonable to suppose that electrical boats may be found

Digitized by Google

useful for various purposes, such as pleasure yachts; and fitted up as torpedo boats for night attack, being perfectly noiseless, and without funnel or fire to betray their existence, they would seem to be eminently suitable.

To what extent the electrical system as regards its application to propulsion may in the future develop it is clearly impossible for anyone to foretell, but if the launch which I have had the honour to describe is to be looked upon as a link in the chain of advance, I would desire to add that the credit belongs to the electrical engineers with whom I had the pleasure to be associated.

## A HISTORY OF ELECTRIC TELEGRAPHY TO THE YEAR 1837.

BY J. J. FAHIE, MEMB. SOC. TEL. ENGS. AND ELECS.*

(CONTINUED FROM PAGE 299.)

### CHAPTER VII.

### TELEGRAPHS BASED ON ELECTRO-MAGNETISM AND MAGNETO-ELECTRICITY.

"The invention all admired; and each how he
To be the inventor missed;—so easy seemed
Once found, which yet unfound most would have thought
Impossible."—Milton's "Paradise Lost," book vi.

### 1836.—STEINHEIL'S TELEGRAPH.

The apparatus last described was, as we have said, established for other than telegraphic purposes, and it was for this reason that Gauss, unable himself to afford the time, invited Steinheil, of Munich, to pursue the subject, and endow with a practical form an invention which he believed capable of great results.

The perfection to which this ingenious inventor brought Gauss and Weber's telegraph has rendered it as much, or more, his than theirs. His own estimate, however, of the changes effected in the telegraph erected at Munich towards the end of 1836 is very modest and is worth quoting:—"To Gauss and Weber," he says, "is due the merit of having actually constructed the first simplified galvano-magnetic telegraph. It was Gauss who first employed magneto-electricity, and who demonstrated that the appropriate combination of a limited number of signs is all that is required for the transmission of intelligence.† Weber's discovery that a copper wire 7,460 feet long, which he had led across the houses and steeples of Göttingen, required no special insulation was one of great importance, and at once established the practicability of a galvanic telegraph in a most convenient form.

"All, therefore, that was required was (1) an appropriate method of inducing, or exciting, the galvanic current, with the power of changing its direction without the need of any special contrivances; and (2) a mode of rendering the signals audible [or legible]. The latter was a task that apparently presented no very particular difficulty, inasmuch as in the very scheme itself a mechanical motion—namely, the deflection of a magnetic bar—was given. All that we had to do, therefore, was to contrive that this motion should be made available for striking bells, or for marking indelible dots.

"This falls within the province of mechanics, and there are therefore more ways than one of solving the problem. Hence the alterations that I have made in the telegraph of Gauss and Weber, and by which it has assumed its present form, may be said to be founded on my perception and improvement of its imperfections. I by no means, however, look on the arrangement I have selected as complete; but as it answers the purpose I had in view, it may be well to abide by it till some simpler arrangement is contrived."‡

We condense the following account of Steinheil's apparatus from an English translation of the author's own classical memoir, which appeared in Sturgeon's *Annals of Electricity*, for March and April, 1839.*

"The telegraph is composed of three principal parts:—

"1. A metallic connection between the stations.

"2. The apparatus for exciting the galvanic current.

"3. The indicator, or receiving apparatus.

#### "1. *Connecting Wire.*

"The conducting chain of the telegraph erected here consists of three parts—one leads from the Royal Academy to the Royal Observatory at Bogenhausen, and back. The total length of its wire is 32,506 feet, and the weight amounts to 260lbs. [*sic*]. Both wires (there and back) are stretched across the steeples of the town at a distance apart of 4 feet 1 inch. The distance from support to support ranges from 640 to 1,279 feet: this is undoubtedly far too great for a single-strand wire, inasmuch as the ice that forms upon it materially increases its weight, and considerably augments its diameter, so that it becomes liable to be torn asunder by high winds. Over those places where there are no high buildings the wire is supported upon poles forty or fifty feet high, which are let five feet into the ground, and at the top of which it is fastened by twisting on cross wooden bars. At the points of support the wire rests on pieces of felt.

"A second portion of the conducting chain leads from the Royal Academy to my house and observatory in the Lerchenstrasse. This is of iron wire, its length, there and back, is 5,745 feet, and it is stretched over steeples and other high buildings, as has already been described.

"Lastly, a third portion of the chain, running through the interior of the buildings connected with the Royal Academy, leads to the mechanical workshop attached to the cabinet of Natural Philosophy. It is composed of a fine copper wire 598 feet long, let into the joinings of the floor, and, in part, imbedded in the walls.

#### "2. *Apparatus for Generating the Galvanic Current.*

"Hydro-galvanism, or the galvanic current generated by the action of the voltaic pile, is by no means fitted for traversing *very long* connecting wires, because the resistance in the pile, even when many hundred pairs of plates are employed, would be always inconsiderable compared with the resistance offered by the wire itself. The principal disadvantages, however, attendant on the use of the pile, or trough apparatus, are (1) the fluctuations of its current, and (2) its speedy loss of power.

"All these difficulties are got over by having recourse to Faraday's important discovery of magneto-electric induction, that is to say, by moving magnets in the neighbourhood of conducting coils. The better way is, not to move the magnets as Pixii does, but rather to give motion to coils of wire in close proximity to a fixed magnet. This arrangement, known as Clarke's, is the one which with some modifications we have adopted.

"The magnet is built up of seventeen horseshoe bars of hardened steel. With its iron armature its weight is about 74lbs., and it is capable of supporting about 370lbs. Between the arms, or poles, is fastened a piece of metal which supports the axis on which the coils revolve. These coils, of which there are two, have in all 15,000 turns of silk-covered wire, a metre of which weighs 15½ grains. The two ends of the wire are passed up through the interior of the axis, and terminate in two hook-shaped pieces which just dip into semi-circular cups of mercury, separated from each other by a wooden partition. From these cups there proceed short wires to which the line wires are connected. The mercury, owing to its capillarity, stands at a higher level in the cups than the partitions, so that the terminal hooks pass over the latter without touching them whenever the coils are revolved. The hooks are thus brought into the cups alternately at every half turn of the coils, and as a consequence the induced current preserves its sign as long as the coils are turned in one direction, and changes it on the motion being reversed. The current, as we shall see when treating of the indicator, should only be permitted to act during as short a time as possible, while during that time it should have the greatest intensity we can give it.

"In order to cut off the inductor when not in action, its axis is made to carry a cross-piece of metal, at right angles to the terminal hooks of the coils, which, when the inductor is at rest, dips into the mercury cups. Whence it follows that the current, on being transmitted from any other station, passes directly from one cup to the other without traversing the wire of the inductor coils. In order to put the coils in motion without trouble a fly-bar terminating

---

* The author reserves all rights of translation.

† Steinheil was apparently unaware of all that Baron Schilling had done in this direction.

‡ To Steinheil's lasting honour be it said that when, some ten years later, "a simpler arrangement" in the shape of Morse's telegraph *was* brought to his attention he was the first to appreciate it, and to urge upon the Bavarian Government its adoption, to the abandonment of a portion of his own beautiful system.

*Apropos* of this, we find an amusing story in Reid's "Telegraph in America," pp. 85-6:—"The (Morse) relay could not be patented in Germany, and therefore could not with safety be exposed. In 1848, two young Americans had gone there with Morse machinery, and built a line from Hamburg to Cuxhaven, a distance of 90 miles, for the transmission of marine news. The line worked charmingly, the registers clicked out loud and strong at either end, but the relays were carefully concealed in locked boxes. The German electricians scratched their heads and wondered. Finally Steinheil was sent forward to reconnoitre; he looked carefully around, and his keen eyes soon detected the locked boxes. He asked to see their contents, but the view was courteously declined. So he returned and reported that the Yankees kept their secret locked, but that the action was magnificent. And when at a later date he *did* know all, he showed the grand stuff of which he was made. He gave Morse his hand, confessed himself beaten and the two were friends for ever after."

* Vol. III., pp. 439-52, and 509-20. See also *Comptes Rendus*, September, 1838; and Shaffner's *Telegraph Manual*, New York, 1859, pp. 157-78. Shaffner says that "the first published notice of this important invention will be found in the third volume of *The Magazine of Popular Science*, in a letter from Munich, under date December 23, 1836." This letter appears on pp. 108-10, is chiefly concerned with electro-magnetic experiments, and in the last two paragraphs briefly mentions Steinheil's telegraph.

Digitized by Google

in two metal balls is attached horizontally to the vertical axis of the coils.

"At every half turn a spark occurs as the hooks of the coils leave the mercury. As this is for many reasons objectionable, we have latterly designed a commutator of a far simpler construction. The ends of the coil are in this case fastened to two strips of copper let into the periphery of a wooden ring, directly opposite each other. This ring is placed upon the axis of the coils, and made fast to it by clamps, and the two ends of the line wire are so disposed as to press like springs against the copper strips as the coils are revolved. With this arrangement the ends of the coils are in metallic connection with the line only during a small portion of each revolution, while during the rest of the time the metal cross-piece, with which also the wooden ring is provided, brings the two ends of the line wire into direct connection. This form of commutator, in which mercury is entirely dispensed with, is, on account of its greater simplicity and durability, preferable to the arrangement just described, and is employed in the apparatus of the stations at Bogenhausen and in the Lerchenstrasse.

"3. *The Indicator.*

"The indicator contains two magnets, movable on axes, which are applicable either to strike bells, or to note down signals. Round a frame formed of sheet brass are wound six hundred turns of the same insulated copper wire as is used in the inductor. The magnetic bars are so placed that the north pole of the one is presented to the south pole of the other. To these ends are screwed two slight brass arms, supporting little cups which are provided with extremely fine perforated beaks. When printing ink is put into these cups it insinuates itself into the beaks owing to capillary attraction, and, without running out, forms at their orifices a projection of a semi-globular shape. The slightest contact, therefore, suffices for noting down a black dot.

"Two plates, or pins, prevent the magnets from being deflected in a direction opposite to that in which they are to print, as the deflection by the current would otherwise cause them to swing, and perhaps record false dots while thus oscillating. As a further check to these oscillations, and in order to bring back the bars quickly to their normal positions after each deflection, recourse is had to smaller movable magnets whose distance and position with regard to the others are to be varied until the desired effect is produced. Owing to the disposition of the magnet bars and the controlling action of the pins, a current sent through the coil deflects only one magnet at a time, the other being simply pressed tightly against its pin; and on the current being reversed, the reverse takes place, the last-mentioned magnet being deflected, while the first is held back.

"Much nicety is required in obtaining the magnets of exactly the right size. They must not, for example, be too large, because their inertia would be too great; nor too small, because then their mechanical force would not be sufficient for printing or sounding the signals.

"For the recording of the signals, a flat surface of paper must be kept moving with a uniform velocity in front of the little beaks. The best way of doing this is to employ very long strips of the so-called endless paper, which is to be wound round a cylinder of wood, and then cut upon the lathe into bands of suitable width. One of these strips of paper must be made to unwind itself from a cylinder, pass close in front of the beaks, run along a certain distance in a horizontal position, so that the dots noted down may be read off, and lastly wind itself up again on to a second cylinder. This second cylinder is put in motion by clockwork, the regularity of whose action is insured by a centrifugal fly-wheel.

"If this apparatus be employed for producing two sounds easily distinguishable to the ear by striking on bells, it will be right to select clock-bells, or bells of glass, both of which easily emit sounds, and whose notes differ about a sixth. This interval is by no means a matter of indifference. The sixth is more easily distinguished than any other interval; fifths and octaves would be frequently confounded by those not versed in such matters. The bells are to be supported on little pillars, and their position with respect to the bars is to be determined by experiment. The knobs let into the bar for striking the bells must give the blow at the place which most easily emits a sound. They are not, however, to be too close to the bells, as in that case a repetition of the signal can easily ensue. A few trials will soon get over this difficulty.

"It is evident that the same magnetic bars cannot be at once employed for striking bells and for writing, the little power they exert being already exhausted by either of these operations. But to combine them both, all we have to do is to introduce a second indicator coil into the chain; this can, however, only be done at the cost of an increased resistance, and, in order that this increase may be as little as possible, it would in future be better that the coils of the indicator should be made of very thick copper wire, or of strips of copper plate.

(TO BE CONTINUED.)

## THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

MEETING HELD MARCH 27TH, 1884.

The President, Professor G. ADAMS, announced that this society, in common with some others, had been invited to hold a conference at the International Health Exhibition, and that the council were now considering what shape the practical acceptance of this invitation should take. He might say, however, that in all probability electric lighting for domestic purposes would be the subject chosen for discussion at their conference, as being most appropriate for an exhibition devoted to health.

Mr. MASSEY then read a detailed and written reply to the objections and criticisms offered to his paper at the last meeting. He contended that it was more important to prove the practicability of lighting a railway train by electricity in the manner he had succeeded in doing than to determine the precise cost of introducing the system on all classes of railways. He had proved the practicability, and he was still of opinion that his method would in the long run prove the most efficient, and, indeed, the only practicable method for general acceptance. As to Mr. Preece's suggestion, he, Mr. Massey, doubted the existence of any spare energy for the pumping of air into reservoirs by trains in motion; and to effect this object economically the trains would have to be always going down hill. He calculated that 70 horse-power would be expended by that scheme to do the work of 7 horse-power. He agreed that there should be two lamps, but they need not both be burning; one could be in reserve, to be switched in if the other failed. Where a railway station is properly lighted the inconvenience of the train lights being temporarily extinguished would be little felt. The general result of the discussion had confirmed him in the belief that a separate engine carried in the train to feed the lights would be the best. As to the cost of fitting carriages belonging to various companies with the necessary wires and appliances, he believed that this difficulty had been got over in the case of air brakes. Mr. Massey concluded with some strong observations upon secondary batteries, which, he said, had done more to delay the progress of electric lighting than all other causes put together. The proprietors of that precious invention acted the part of the dog in the manger, continually asking that we should do nothing in the matter of electric lighting until their secondary battery was perfected. It was always going to be perfect on the 1st January next, but several Januaries had passed away, and its perfection was seem as far off as ever.

A vote of thanks having been warmly accorded to Mr. Massey,

Professor G. FORBES, F.R.S.E., then read a paper of unusual length, "On the Proportion which ought to Subsist between the Size of Conductors and the Strength of Currents." Professor Forbes, after commenting generally upon the injury done to insulation by over-heating the conductor, especially with large installations, and to the practical superiority of large conductors as illustrated in the case of gas-mains, said that we must face the problem of carrying, say, 70,000 amperes of current without overheating if the installations contemplated under the provisional orders scheme of last year were to be carried out. The received notion as to the proportion current should bear to area of wire was theoretically fallacious, and his experiments had proved it to be so in practice. The rules laid down by this society and adopted by the insurance companies were based on a misapprehension and calculated to render economical electric lighting impossible. Mr. Forbes then in detail considered the heating effects upon bare overhead wires, upon cables overhead, upon subterranean wire, subaqueous cables, and lastly upon coils of wire. The first was cooled by radiation, and to a large extent so was the second class of conductors, whilst on subterranean and subaqueous cables the heat was dissipated by absorption. These facts had not been allowed for in the various tables and calculations hitherto made public for the guidance of electrical engineers, nor had any notice been taken of the condition of the wires as regards brightness or dulness, which materially affected the dispersal of their internal heat. The superficial area of the wire had a great deal to do with the heating effects of the current passing through it, as had been shown by the experiment of flattening a round wire into a broad band, whereupon the heat became no longer perceptible, the explanation being that the increased surface got rid of the heat by radiation. So also in the case of insulated wires, the area of convection provided by the thick insulating material permitting a considerable increase of current without danger. Absorption also played its part in carrying away the heat from covered conductors. In underground wires the effect of absorption was very great indeed, and it would take many hours to heat the conductors so situated. He recommended the use of iron for conductors.

Mr. Blakesley's paper on a similar subject had to be postponed until the next meeting, which is fixed for the 24th April.

## INAUGURAL ADDRESS.

Delivered by Professor W. GRYLLS ADAMS, F.R.S., 10th Jan., 1884.

(CONTINUED FROM PAGE 479.)

Let me borrow another instance from the energy of motion in a resisting medium. Before Froude made his celebrated experiments on the resistance to the motion of ships through the water, it was supposed by mathematicians that, in consequence of the perpendicular pressure of a fluid against the ship, there was work done by the ship moving through the water in removing the water out of its path. Not unfrequently the friction against the side was supposed to be so small in comparison with this that it was entirely neglected. Now Froude has shown that nearly all the energy spent in driving the ship through the water is spent in overcoming the work of friction against the sides, and the internal friction or viscosity of the water. The same is also true of the motion through gases, part of the energy in these cases being spent in producing eddies in the fluid.

In the progress of electricity the steps are clearly shown which usually mark the progress of any science. At first there is an accumulation of observations or of facts, which may appear wonderful in themselves and unconnected with one another; these may be classified and arranged under their respective heads, but they acquire a new significance when they are shown to be instances of a more general law, which binds them altogether, and forms a groundwork for the pursuit of further and wider investigation.

The discovery by Faraday, in 1831, of the time interval before an electro-magnet gets up to its full strength, and the experiments of our late president on induction currents are but instances of the law that all electro-magnetic phenomena require time for their development. Maxwell, in his excellent treatise on electricity and magnetism, has put this matter very clearly, and has shown that the velocity of transmission of electro-magnetic influence is the same as the velocity of light on the wave theory; he has also fully shown how the different electro-magnetic phenomena are related to the principles of energy—that, in fact, the work done by an electromotive force acting on a conducting circuit is energy of motion; that part of this energy is spent in producing electro-magnetic phenomena, such as the motion of conductors, the revolution of the armature of a dynamo machine used as a motor; that another part is spent in overcoming the resistance of the circuit, and that this part is converted into heat; and that the remainder is spent in increasing the energy of motion of the current, giving rise to the phenomena of induction currents.

The rapid progress in the discovery of the principles of electricity, and in its practical applications, is especially due to the fact that those who have taken the lead, both in theory and in practice, have been men who have seen the full importance of accuracy of measurement in all that pertains to physical science, and, by the instruments which they have invented, have themselves greatly contributed the means of attaining that accuracy in the measurements of electricity.

We could hardly take a better instance of the progress of the theory of electricity, and the methods of overcoming difficulties in its practical application, than the discovery by Sir William Thomson of the law of retardation in submarine cables, followed by his invention of the mirror galvanometer and his siphon recorder. Having found that this retardation is proportional to the square of the length of the cable, and that the disturbance, as it travels, spreads out into a long wave on which any number of little ripples may successively be superposed, he invents the instruments by means of which those ripples could be made to give the message through the cable at a speed which would be practically useful.

When speaking on the subject of the importance and the methods of accurate measurement in electrical science, and on its relation to the science of energy, it is right that I should draw attention to the work of the late Sir William Siemens, whose loss will be deeply felt, not only by his family and friends, but in the scientific world and in every branch of the profession of engineering. His scientific labours extended into several branches of science—perhaps I should rather say that he approached the other sciences through the science of energy. He was a practical engineer, who, while not neglecting the teachings of experience, yet felt the full importance of founding his practice on a true scientific basis, and who has been distinguished for the way in which he has devoted himself to the storing up of wasted energy. His first visit to England took place in the year 1843—the year in which Joule firmly established the principle of conservation of energy by his experiments on the friction of water and on the heat generated by the magneto-electric machine. The statement made by Joule, that "wherever mechanical force is expended, an exact equivalent of heat is always obtained," was not readily received by the leaders in science, even after a second important paper on the subject in 1847 (when Sir William Thomson's attention was first drawn to the subject), yet in that very year Sir William Siemens was applying the principle to practice by storing up heat in his regenerative condenser; and in 1853, in his paper on "The Conversion of Heat into Mechanical Effect," he defines a perfect engine to be one in which all the heat applied to the elastic medium is used up in causing its expansion within the cylinder, leaving no heat to be thrown into a condenser or into the atmosphere. From this time his attention was directed to the principle of regeneration as applied to condensers and steam engines, and a few years later, with his brother Frederick, he invented the regenerative gas furnace. Nothing but the conviction of the importance of preventing the waste of energy would have carried him through the first unsuccessful attempts to make steel on the open hearth of a regenerative gas furnace; but in 1867 his labours were crowned with success, when steel of good quality was produced and shown at the French Exhibition. Our ideas of the actual temperature of furnaces have become more definite since Siemens constructed his pyrometer and his electrical resistance thermometer.

It was early in the year 1867 that Sir Wm. Siemens brought before the Royal Society the results of researches, based on an idea thrown out by his brother, Dr. Werner Siemens, whereby he established the principle which forms the basis of all dynamo-electric machines.

An idea had been advanced by Hjorth in 1854, that the current from the armature of a magneto-machine might be sent round certain electro-magnets so placed as to strengthen the magnetic field of the permanent magnets, but this idea had been lost sight of, and in February, 1867, two very important papers were brought before the Royal Society on the same evening, one by Sir Charles Wheatstone and the other by Sir William Siemens, in which the principle of the action of dynamo machines was fully set forth. We may call it the principle of the regenerative action of electric currents. On the same evening Sir C. Wheatstone pointed out the great advantages of the divided circuit arrangement, which is now adopted in shunt dynamo machines—advantages which (as shown by Sir William Siemens in his recent paper before the Royal Society) greatly increase the steadiness and efficiency of the machines.

The past year has seen great advances made in the application of electrical energy to metallurgy and in the electrical transmission of power; in these branches Sir William Siemens was always found in the front rank. Time will not now admit of my considering fully the speculations as to a fan-like solar action which Sir William Siemens has recently put forward to restore and keep up solar energy. One cannot help seeing in this, as in all the work of his busy life, how difficult to him was the idea of wasted energy.

It has been well said that solar heat is the principal source of energy available to man. This solar heat promotes evaporation and lifts the vapour to the mountain tops, whence it descends again in streams which may be regarded as vast stores of energy of motion, readily convertible into useful work by means of turbines, with a loss of only 25 per cent. *i.e.*, with an efficiency of 75 per cent.

The earth has been storing up solar energy for ages in our coal-fields. This energy, again converted into heat by the combustion of the coal in oxygen or in atmospheric air, may be converted into mechanical work, and made use of by means of heat engines; but in every conversion of energy there must always be some loss, and especially in the conversion of heat into work, because in the form of heat energy is most readily dissipated.

In approaching the practical applications of this science of energy, let me first draw attention to the conversion of heat into work, and to the efficiency of heat engines.

In every form of engine which is practically useful for the conversion of heat into work, we have to deal with a substance at two different temperatures, and the work is done by the expansion of the substance against the external pressure of a piston by means of which the work is accomplished—thermo-electric engines being as yet possible, but not actual sources of supply.

Thus, in a hot-air engine, heat is applied to air enclosed in one part of a cylinder; this air expands and drives back a piston, so doing work and losing its heat. If the air is further cooled on expanding by means of a refrigerator, a greater amount of work may be done, the amount being directly proportional to the difference of temperature of the air in its hot and cooled state—*i.e.*, the work done is proportional to $(T - t)$. The efficiency of the engine is the ratio of this work to the total heat given to the air—*i.e.*, if T is temperature from absolute zero, the efficiency of the engine is $\frac{T-t}{T}$. Hence the efficiency of such an engine depends on the difference of temperature through which it works.

By the second law of energy, or thermo-dynamics, it is established that in all heat engines the work which a given quantity, Q, of heat can actually produce is $Q \times \frac{T-t}{T}$, or the efficiency of all such engines cannot be greater than $\frac{T-t}{T}$.

Now, in the steam-engine the temperature of vapour in the cylinder is somewhat less than in the boiler, and some portion of the heat is lost by conduction and by frictions; also the pressure of steam increases so rapidly with temperature that the temperature attainable is limited from the danger of explosion of the boiler. By employing superheated steam separated from the water in the boiler, a higher temperature may be attained and the efficiency of the engine greatly increased. For high-pressure engines the usual temperature is not higher than 150°C., so that the range of temperature is only about 100°C., and the efficiency certainly less than $\frac{100}{423}$, or ·235, *i.e.*, less than 24 per cent. This is the greatest efficiency which would be possible in a perfect engine, working between the temperatures of 150°C. and 50°C., supposing the temperature of the steam to be lowered by its expansion in the cylinder to the temperaature of 50°C. This would mean that the steam must be allowed to expand to twenty-six times its original volume, which would be impracticable, and, if it were possible, would introduce other serious causes of loss of energy.

In the very best results which have been attained the temperatures between which steam-engines have been worked are such as to give a theoretical efficiency of from 30 to 33 per cent. supposing the engines to be perfect engines. With the best engines the actual efficiency is very much less than this, which represents what the efficiency would be in a perfect engine, *i.e.*, where all the heat applied to it is converted into useful work.

The best steam-engines have only a practical efficiency of from 10 to 13 per cent.

The question whether the hot-air-engine will offer greater advantages than the steam-engine must depend upon whether it can be worked at a

Digitized by Google

very high temperature or not, for only in that case can its efficiency be greater.

With the sterling hot-air engine the temperature is such that a pressure of about 37lb. per square inch is obtained, and the efficiency has been found to be about 30 per cent. But the difficulties of heating the air, without raising the temperature of the cylinder so high that it was burnt out, have prevented this engine from being much used.

In connection with the production of electrical energy, considerable attention has for some time past been given to another form of heat engine, in which an explosive mixture of ordinary coal gas with air is compressed and then exploded inside a cylinder. By this means very high temperatures may be reached, and hence a considerable amount of efficiency may be expected to be attained.

In the working of the Otto gas engine, the forward motion of the piston draws in air and an explosive mixture of air and gas; then the return of the piston compresses this mixture into less than half the length of the cylinder, the charge is then ignited and the explosion takes place, raising the temperature and pressure to their highest value; the piston is driven forward, and the pressure falls, then on the return stroke the exploded mixture is driven out of the cylinder. The work done in the explosion and expansion of the gases takes less than a quarter the time of two revs.

In the Clerk gas engine a second cylinder is added to supply the explosion cylinder with the explosive mixture, so as to get an explosion at every revolution. During the explosion and expansion in the explosion cylinder a piston has been drawing in first air and gas, and then air into the second or displacer cylinder, and at the beginning of the return stroke they are driven into the explosion cylinder, the air first to clear out the used gases, and then the explosive compound, which is compressed at the end of the stroke to a pressure of nearly three atmospheres. The explosion then takes place, raising the temperature and the pressure to their highest value, and the piston is driven forward.

In these gas engines, although there is great loss of heat through the cylinder, which must be surrounded with a water jacket with a constant supply of cold water, yet the form of the curve of pressure keeps nearly up to the isentropic line, as if no heat were allowed to escape. This is accounted for by supposing that the temperature of dissociation of the gases is reached, or that at the temperatures reached a portion of the gas is disassociated, which enters into combination again when the pressure is gradually diminished by the forward motion of the piston. In this way the gas gradually burnt supplies the heat lost through the sides of the cylinder. Now, the temperature may possibly reach to 1,800° or 2,000° C., and indeed in gas engines has been found to reach 1,500° C.; hence considerable efficiency may be attained, notwithstanding the fact that the exploded mixture would have its pressure somewhat diminished by an amount depending upon the contraction in volume of the gases forming the explosive mixture when they are exploded under constant pressure. With hydrogen, or with a mixture of hydrogen and carbonic oxide only, burnt in oxygen, this contraction would amount to one-third of the whole, and so the pressure attained would only be two-thirds of the pressure, supposing there were no contraction. If other gases are mixed with these, as in ordinary gas, then the pressure will not be so much reduced from this cause, but there will always be some such reduction from the pressure which would otherwise be attained when the gases are exploded. Were there no dissociation, a very much higher temperature would be attained than is actually observed in gas engines.

Making the supposition that the highest temperature reached is about 1,500°C., and that explosion takes place at once through the whole of the space occupied by the gas, the pressure at the first instant after explosion would be five or six times the pressure before explosion. If the gases be compressed to a pressure of nearly three atmospheres before explosion, the pressure of the exploded mixture is at first about fifteen atmospheres at a temperature of 1,500°C. Supposing that the expansion of the exploded gases is allowed to continue until the pressure is equal to the pressure of the atmosphere, the volume of the expanded gases would be more than six times their volume before expansion; and the temperature of the mixture, supposing no heat to have been lost through the walls of the cylinder, would be reduced to about 370°C.

As it would be inconvenient to go beyond the volume at which the mixture before explosion was at atmospheric pressure, *i.e.*, where the ratio of volumes is 3 to 1, under these circumstances the temperature at which the products would be discharged from the cylinder would be about 1,060° C. Taking into account the loss of heat by conduction and frictions, the temperature would be considerably lower. This would give an efficiency of about 25 per cent. With very high temperatures, such as those in gas engines, the loss through the sides of the cylinder must be very great, for the cylinder must be kept cool in order that the piston may work in it, so that it is impossible to make use of the principle of the regenerator in this form of gas engine to heat up the entering gases.

Let me illustrate my remarks on this subject by some results obtained from the experimental tests made on gas engines at the Crystal Palace, which were carried out by Mr. H. Darwin, Mr. F. J. Sprague, Mr. Spagnoletti, Mr. Crampton, and myself—Mr. Sprague having devoted himself most zealously to the work.

Assuming the values given by Mr. Clerk in his paper before the Institution of Civil Engineers for the heat evolved on the combustion of ordinary gas, we may arrive at the practical efficiency of the Otto gas engine.

One pound of gas at 17° C. measures 35·5 cubic feet, and evolves on combustion 12,500 units of heat.

Now, in the Crystal Palace experiments with the 12 horse-power Otto gas engine, the quantity of gas used per hour was 533·4 cubic feet, or 15lb. Hence the heat absorbed per minute is $\frac{12{,}500 \times 15}{60}$, or 3,125 units.

The work done per minute upon the piston (which is 12 inches in diameter, and has a 16-inch stroke), at the rate of 158·7 revolutions per minute, with a mean pressure of 62·2lbs. on the square inch, is $\frac{158{\cdot}7}{2} \times 62{\cdot}2 \times \frac{4}{3} \times \frac{22}{7} \times 36$, or 744,800 units of work.

This is equivalent to 536 units of heat. Hence the theoretical efficiency is $\frac{536}{3{,}125}$, *i.e.*, ·1715, or 17 per cent. The available indicated horse-power is 22·56, and the horse-power, as shown by the Froude dynamometer, is 18·31. Hence the practical efficiency $= \frac{1{,}831}{2{,}256} \times {\cdot}1715 = {\cdot}1392$, or 14 per cent. The gas used per brake horse-power is 29·1 cubic feet.

With the 16 horse-power gas engine the quantity of gas used per hour was 841·6 cubic feet, or 23·71lbs. Hence the heat used up per min. is

$$\frac{12{,}500 + 23{\cdot}71}{60}, \text{ or } 4{,}940 \text{ units,}$$

the diameter of piston being 13 inches, length of stroke 1½ feet, mean pressure 63·08 per square inch, revolutions 151·37 per min. The work done per minute upon the piston is

$$\frac{151{\cdot}37}{2} \times \frac{7}{4} \times 63{\cdot}08 \times \frac{22}{7} \times \left(\frac{13}{2}\right)^2, \text{ or } 1{,}109{,}000 \text{ units of work, which}$$

is equivalent to 798 units of heat. Hence the theoretical efficiency is ·1615, or 16 per cent. The available indicated horse-power is 33·6. The horse-power on the brake or dynamometer is 27·75. Hence the practical efficiency is $\frac{2{,}775}{3{,}360} \times {\cdot}1615$, *i.e.*, 1334, or 13⅓ per cent. The gas used per brake horse-power is 30·3 cubic feet. It will be seen that 82·6 of the indicated horse-power appears on the dynamometer.

With the two horse-power Otto gas engine, the quantity of gas used per hour was 95·8 cubic feet, or 2·7lb. Hence the heat generated per minute is $\frac{12{,}500 \times 2{\cdot}7}{60}$, or 562·5 units. The diameter of the piston is 5·75 inches, length of stroke 1 foot, mean pressure 54·31 per square inch, revolutions 160·3 per minute. The work done per minute upon the piston is

$$\frac{160{\cdot}3 \times 1 \times 54{\cdot}31 \times 22 \times (5{\cdot}75)^2}{2 \times 7 \times 4} = 113{,}100 \text{ units of work nearly,}$$

which is equivalent to 81·37 heat units, or to 3·42 horse-power. Hence the theoretical efficiency is 1,446, or 14½ per cent. The horse-power on the brake or dynamometer is 2·87; hence the practical efficiency is

$$\frac{287}{342} \times {\cdot}1446, \textit{ i.e.}, {\cdot}1214, \text{ or 12 per cent.}$$

The gas used per brake horse-power is 33·4 cubic feet.

It will be seen that 84 per cent. of the indicated horse-power appears on the dynamometer.

(TO BE CONTINUED.)

## THE GERMAN UNION TELEGRAPH AND TRUST COMPANY (LIMITED).

The thirteenth ordinary general meeting of this Company was held on Thursday at the offices, 65, Old Broad-street, E.C., Sir James Anderson in the chair.

Mr. WM. PAYTON (the secretary) read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN said: I am very glad that I have almost nothing to say in reference to the report. I might make what I dare say would be considered by other chairmen a model sort of speech, inasmuch as I can say that we have had no repairs to make during the past year, and we have had at the same time an increase of revenue. The main items in the report are, you will observe, that we have spent £26 more this year than last year, and that has arisen from our having to get new register books; but the most satisfactory part of the report—next to the increase of traffic at all events—is the fact that we have £42,500 of reserve and £20,500 of unexpended capital. The only outlay incurred last year has been in making a new station at Lowestoft, the old one having been washed away by the heavy gales. We had to erect a new station, or cable house, of a substantial character, such as we can work in when the traffic requires any increase of speed. I do not know, gentlemen, that there is anything else worth calling your attention to. You are all aware that we laid another cable from Valentia to Emden about two years ago, and I am glad to say that the revenue having responded to the outlay we are able to pay you nearly 6 per cent., which is a half per cent. more than last year. I may add that as far as we can judge there is every probability that we shall continue in the same prosperous condition, always of course subject to any interruptions at any time to which submarine cables are more or less liable. With these remarks I beg to move, "That the report and accounts for the year ending 31st December, 1883, submitted to this meeting be, and they are hereby received and adopted, and that a dividend of 6s. per share be declared payable this day free of income-tax, making with the previous distribution of 5s. 9d. a total dividend for the year of 11s. 9d., or at the rate of £5 17s. 6d. per cent. per annum."

Mr. HERMANN GUSTAV ERICHSEN seconded the motion, which was carried unanimously and without discussion.

The CHAIRMAN: The next resolution I have to propose is, "That Mr. Erichsen be, and he is hereby re-elected a director of this Company."

The motion was seconded by Count OSCAR VON REICHENBACH and carried *nem. con.*

Mr. GRIFFITHS: Mr. chairman and gentlemen, I have always found that when the report and balance-sheet present a satisfactory aspect the

Digitized by Google

attendance of shareholders is not very large. That non-attendance in one respect is a good sign, as it shows the confidence of the shareholders in the gentlemen who have carried on the business of the Company. There is no doubt that one test of the accuracy of the business operations—and the most important test of all—is that which is furnished by the balance-sheet and the revenue account certified by your auditors. The absence of shareholders proves our confidence in the direction, and I hope we shall also prove our confidence in the accuracy of these accounts by re-electing our auditor. I certainly myself have nothing to say against him, but, on the other hand, the results which have accrued are certainly in favour of the Company, and his own reputation is in favour of the accuracy of the accounts ; therefore, with much pleasure, I move the re-election of our auditor, Mr. Henry Dever—a name, I believe, not unknown in city circles—with a remuneration of £25 for the current year.

Mr. JOHN PENDER, M.P. : I have great pleasure in seconding the re-election of Mr. Dever as our auditor. I am perfectly satisfied that any accounts he deals with will give satisfaction to all parties concerned.

The motion was carried unanimously.

Mr. GRIFFITHS : Perhaps I may be permitted to make a remark. Promptness certainly is the soul of business. I think on this occasion we have been unusually prompt, but we ought not to be so prompt as not to record our thanks to those who have been the cause of our success during the past year. No doubt a telegraph company requires more than usual skill in its management, not only a knowledge of the resources of the home country, the population and power to produce wealth, the progress it is likely to make, the progress of commerce and interchange of commodities, but a telegraph director also requires that he should have general experience in these matters as they may arise in the country to which the telegraph messages are sent from our own country, and from which we receive these messages. We are fortunate in having upon our Board gentlemen of known reputation in this country, and I think we are equally fortunate in having on our Board gentlemen whom we may presume to be thoroughly acquainted with the resources and requirements of Germany. The affairs of our Company have been well managed during the past, and it is only a proper mark of respect and gratitude to both the directors who rejoice in our English nationality, and to those who are members of their own fatherland, that we should record our thanks to them on the present occasion.

The motion was seconded by Mr. JOHN PENDER, M.P., and carried unanimously.

The CHAIRMAN : Gentlemen, in the name of myself and colleagues, I thank you for this expression of confidence.

The proceedings then terminated.

## THE AUSTRALASIAN ELECTRIC LIGHT, POWER, AND STORAGE COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Friday, the 28th ult., at the offices, 41, Coleman-street, E.C., Mr. Randolph C. Want in the chair.

Mr. J. H. DUNCAN (the secretary) having read the notice convening the meeting,

The CHAIRMAN said : Gentlemen, you have now heard the object of our calling you together, and I think that we shall be able to receive your congratulations before I have finished upon the successful issue of these negotiations with the local company of Melbourne. Perhaps, before going further, I may take this opportunity of thanking those gentlemen who are not here for having so liberally sent us their proxies. It is gratifying, of course, at all times to feel that we possess the confidence of the general body of our shareholders, and they have evidenced this, in the first place, by very liberally answering to the calls made at the last meeting, and since then by sending in their proxies. Of course this has nothing to do with your approving the scheme ; I merely take this opportunity of thanking them for the continued evidence of their confidence in our administration. Before I conclude I shall ask the secretary to read out to you the heads of the agreement that we are going to deal with, and I propose now simply to deal with the principles on which the thing is based. I may explain that some years ago, previous to 1881, there was a small business being conducted in Melbourne by an individual, Mr. Selby, who had succeeded so far that it was found desirable by a number of gentlemen to form themselves into an association or company, and purchase from him the business which he had started, and for that they paid him the not inconsiderable sum of £5,000. This company, when we arrived in the colony with our representatives, we found to be steadily pursuing their work, and, as a matter of fact, they had been not only working steadily but at a profit, and paid a dividend. I will not say it has been kept up since, because we came into the field as competitors. It is this competition that has really been the stumbling-block in the way of the progress of either of us. Negotiations have been going on for a long time to see if we could not bring our two interests together. It has been a severe struggle, because each thought himself master and commander of the fort. Only last week we were in receipt of telegrams saying that a provisional agreement had been entered into between the general manager of our Company out there and the Board of the other company, subject, of course, to confirmation here by yourselves at this meeting. There is one feature to which much value must be attached, and that is that out there a local company is always in greater favour than any other company, and this Company has not only the power of supplying electric lighting, but can also manufacture all the articles connected with electricity, such as telegraphs, telephones, torpedoes, and things of that nature, and that, of course, to us would be of especial value, because if we send our machinery out there there may occasionally be defects or alterations required to be made, and we hope to find in that a source of benefit. But the great point we look to for our success in this. We are in command of all the newest patents we can acquire. We have found ourselves approached by the very best patentees, and all the work we have done there has been so successful that at last we have been able to wean the other company from the fancied notions that they are able to do the work better than ourselves, and induce them to throw themselves with us into one boat. I will not go into the particulars of the amalgamation, because those are in the memorandum prepared for the purpose, and will be read to you presently by the secretary. As an instance of one of the advantages to be obtained by this amalgamation and by the freedom from competition, I may mention that a very large contract out there is under consideration, and has been for some time, and has been the subject of tenders. We were prepared to submit our tenders, and the local company were of course prepared to do so likewise in competition with ourselves. The matter involves the outlay of a considerable number of thousands of pounds, and we were of course hoping to get it, but since this advance of the negotiations we have received a telegram to state that our Company has withdrawn from tendering, in order to allow the local company to make the tender, on, I dare say, what will be much more advantageous conditions than if we had been in competition with them ; and no doubt the result will be fruitful to us as part owners in the amalgamation. I do not give the name, because the thing has not been decided, and for obvious reasons I will not go into every detail about it. We came, therefore, to the conclusion that for all these reasons the amalgamation is not only desirable, but something to congratulate ourselves upon. Our combined forces we think will prove successful. There is no doubt that the other company possess a great deal of local influence ; their connection is very great, and they have all the material for making good headway. They have a central lighting station, from which we intend, of course, to draw and direct several good contracts. When I say we, I mean they, we merely participating with them. There is another peculiar feature which I could not talk about before, and that is that Victoria indulges in the luxury of Protection. The other colonies do not share the same view ; in the other colonies it is not extended to the electric lighting interests. If they extend the duty to electrical machinery we shall certainly have a great advantage in being in connection with a local company, who make all their plant there, of course to the exclusion of almost all other companies. Then as to the advance that has been made in the matter of the negotiations, I may mention that the negotiations have been going on for a long time. Of course they could not be kept open for months by communications to and from this country, so that our agent out there has signed a provisional contract with the full understanding that we had to come here for your authority and confirmation, and it is for that to-day we have asked you to meet. As a matter of course, nothing is binding unless the vote of the shareholders carries it. It is true we had practically the power to do it as a Board, but we were not likely to do it having promised at the last meeting we would submit it for your authority, and we do so with very great respect.

Mr. J. H. DUNCAN, the secretary, read the provisional agreement :—"The basis of the agreement is the sale to the local company of about £10,000 worth of plant out of the stock at present in Melbourne, in exchange for shares in that company, which will give our Company about one-third of the ownership of the amalgamated business, with an option to complete, on the same terms, the half-ownership, as mentioned below. Our Company accepts a liability to find working capital to the extent of £2,710, the local shareholders contributing at the same time a further amount of £8,400. All compensation between the two companies will cease, as the amalgamated company will be left free to work Victoria alone, the local company retiring altogether from the other colonies, and constituting our Company elsewhere in Australia its sole agents for the Swan lamp. The shares of the Australian Electric Company are principally held locally, and are reported by the general manager as quoted at par ; the shares to be issued to this Company will rank *pari passu* with these. The directors have every reason to believe that important advantages will result from this arrangement, apart from the profits anticipated from the actual investment itself, viz. :—1st. The only active competitor in Australia will be conciliated and united in interests with our Company. 2nd. An electrical factory in working order in the most central city in the colonies will be at our Company's disposal. 3rd. A lighting station, already partly established at Melbourne, will be developed upon a commerical basis, though not immediately on a very large scale, by the amalgamated company. 4th. The rights of the Swan patents will be added to those already enjoyed by our Company. 5th. Important local influence will be secured. 6th. A considerable saving in the standing charges will, before long, become practicable. These and other advantages will be attained at a comparatively small outlay, and by a contribution from the existing stock in trade of the Company at prices which already leave a very fair profit, while the option is secured of completing the half ownership of the local company should it prove the success which there is every reason to believe will be the result of this arrangement."

The CHAIRMAN proposed "That the statement having been submitted of the agreement proposed to be entered into or already provisionally entered into with the Australian Electric Company (Limited) for the amalgamation of this Company's interests in the colony of Victoria with that company, the directors be and they are hereby authorised and requested to carry out the said arrangement."

Mr. LATIMER CLARK seconded the resolution, which was carried unanimously.

A SHAREHOLDER asked whether any addition had been made to the Board since the last meeting? He understood that Mr. Hammond was to have been asked to join.

The CHAIRMAN replied that at the last meeting a resolution was carried

Digitized by Google

that Mr. Hammond should be invited to join the Board, and the directors accordingly asked that gentleman to accept a seat. Mr. Hammond, however, said that he was too much engaged to comply with their request, but, at the same time, he was willing to give the Company the benefit of his assistance and advice in any way in his power. The Board had, in fact, referred to Mr. Hammond on all points on which it was thought desirable to obtain his advice, and he might say that the present scheme had been carried out with Mr. Hammond's entire approval. The directors had not elected any other gentleman, because there was no original shareholder who was qualified whose name had been mentioned at the last meeting. The qualification of a director was 150 shares, and at the last meeting it was suggested that none should be asked to join the Board unless he was an original shareholder with the requisite qualification. Two new directors had been named and appointed in the colony by this Company, Mr. Street and Mr. Hudson, and he thought they had made a very good arrangement in securing the services of those gentlemen. Mr. Hudson was one of the largest railway contractors and engineers, and Mr. Street was connected with one of the leading mercantile firms. Of course they wanted help more in the colony than in this country.

A vote of thanks to the chairman and directors then terminated the proceedings.

## SOUTH EASTERN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Thursday, at the Cannon-street Hotel, Sir Michael Kennedy in the chair.

Mr. ALFRED JERMYN (the Secretary) having read the notice convening the meeting,

The CHAIRMAN moved the confirmation of the following resolution, viz., "That the capital of the Company be reduced from £100,000, divided into 20,000 shares of £5 each, to £51,000, consisting of 400 fully paid shares of £5 each, and 19,600 of £2 10s. each, and that such liability be effected by reducing the liability on each and every of the 19,600 shares to the extent of £2 10s."

Mr. FRY seconded the motion, which was carried, and the proceedings terminated.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY, LIMITED.

NOTICE IS GIVEN that the CABLE between St. Vincent and Pernambuco is REPAIRED, thereby restoring Direct Telegraphic Communication with South America.

RICHARD COLLETT, Secretary.

8, Great Winchester-street, London,
March 28th, 1884.

CITY and GUILDS of LONDON INSTITUTE for the ADVANCEMENT of TECHNICAL EDUCATION.

TECHNOLOGICAL EXAMINATIONS, 1884.

Examinations in Technology will take place at the different Provincial Centres throughout the kingdom, on Wednesday evening, May 28th, 1884, at 7 o'clock.

Secretaries are informed that the latest date for sending in returns of candidates who wish to be examined in May next is Monday, April 28th, after which date no application can be received.

Individual candidates who are unable to arrange to be examined at a Provincial Science Centre can, on application to the director and secretary, be examined in London, at the Finsbury Technical College, Tabernacle-row, E.C.

The examinations will be held in 45 subjects.

A programme containing syllabus of each subject and last year's examination questions can be obtained from the Central Office of the Institute, Gresham College, London, E.C.

PHILIP MAGNUS, Director and Secretary.

MR. ROBERT HAMMOND on THE ELECTRIC LIGHT IN OUR HOMES.

Mr. Hammond will LECTURE at ST. JAMES'S HALL on this subject at Eight o'clock on WEDNESDAY EVENING, the 16th April.

Stalls, 5s.; Balcony, 3s.; Area, 2s.; Admission, 1s. Tickets can be had from Mr. Austin, at St. James's Hall; and from all the West End and City Libraries.

WANTED.—An ELECTRICIAN and ENGINEER, either as sole in charge or as junior under Consulting Engineer. Must be thoroughly up in testing work and good general knowledge.—Apply, stating experience and salary, to "AUSTRALASIAN," J. H. Duncan and Co., Chartered Accountants, 41, Coleman-street, E.C.

A YOUNG MAN (23) WANTS SITUATION. Practical knowledge of Engines and Boilers, and drawing; moderate knowledge of Electricity (theoretical).—Address, W. C., 74, Crescent-road, Plumstead.

JUST PUBLISHED.

Crown 8vo. Cloth, 540 pp., with Illustrations. Price 9s.

A HISTORY of ELECTRIC TELEGRAPHY to the YEAR 1837. Chiefly compiled from original sources and hitherto unpublished documents. By J. J. FAHIE, M.S.T.E.

London: E. and F. N. SPON, 16, CHARING CROSS.
New York: 35, MURRAY STREET.

## NOTES.

BRITISH GUIANA. — The cable between Trinidad and Demerara is now repaired.

THE TELEGRAPH IN QUEENSLAND.—The Roebourne telegraph line has been completed as far as First Station, Flint Cliff.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 4 amounted to £4,673.

THE SOUDAN.—Telegraphic communication with Khartoum is still interrupted, but the line between Berber and Korosco is again working.

THE TELEPHONE IN CINCINNATI.—There are 70 public call rooms in Cincinnati, U.S., where the public can avail themselves of the telephone.

THE TELEPHONE FOR DIVERS.—Orders have been issued that telephones for the use of divers are to be supplied to Her Majesty's ships carrying such men.

APPOINTMENT.—Mr. Henry F. Joel has been appointed electrical engineer by the Leeds Corporation to supervise the fitting of the electric light in the new municipal buildings.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the month of March, 1884, were £1,751, against £1,782 in the corresponding period of last year.

GLOBE TELEGRAPH AND TRUST COMPANY.—The directors of this company announce a dividend of 3s. on the preference shares, and 2s. on the ordinary shares, for the quarter ending 18th inst.

PYRAMID ELECTRIC COMPANY.—A petition for the winding up of this company subject to the supervision of the High Court of Justice is to be heard before Vice-Chancellor Bacon on the 26th inst.

THE ORKNEY CABLE.—The telegraph steamer "Monarch" arrived at Kirkwall on the 4th inst., and was to proceed to Stronsay when the sea moderated and lay a new cable between that island and Sanday.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The estimated traffic receipts of this company for the half month ended the 31st March are £3,490, as compared with £4,275 in the corresponding period of 1883.

EASTERN EXTENSION TELEGRAPH COMPANY.—The traffic receipts of this company for the month of March, 1884, amounted to £35,553, and to £32,970 for the corresponding period of 1883, being an increase of £2,583.

THE MELBOURNE TELEGRAPH OFFICE.—Telegraphic business has increased so rapidly in Melbourne that it has been found necessary to add another story to the General Post Office, Melbourne, at a cost of about £40,000.

PROTECTION OF SUBMARINE CABLES.—A despatch from Lord Lyons, forwarding the convention for the protection of submarine telegraph cables, which was signed at Paris on March 14th, has been issued as a parliamentary paper.

GOOD FRIDAY.—The Post Office notify that in England and Ireland the attendance at most of the provincial telegraph offices on this day will be as on Sundays. In Scotland, however, they will be kept open as on ordinary week days.

DIRECT UNITED STATES CABLE COMPANY.—The directors of this company have determined to recommend the payment of an interim dividend of 5s. per share, being at the rate of 5 per cent. per annum, for the quarter ending March 31, 1884.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending the 4th inst. were £3,711, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The secretary of this company writes that telegraphic communication with Valparaiso, Buenos Ayres, and all telegraph stations in Peru, Chili, the Argentine Republic, Uruguay and Brazil is now re-established, *viâ* Galveston.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company in March, 1884, amounted to £21,920. For the period 1st January to 31st March, 1884, they were £60,600, against £57,194 in the corresponding months of 1883, and £54,369 in the same period of 1882.

THE CITY GUILDS AND TECHNICAL INSTRUCTION.—The Common Council of the City of London have resolved to contribute £1,000 towards the £20,000 required for the equipment of the central institution of the City and Guilds of London Institute for the Advancement of Technical Education.

LONDON CENTRAL ELECTRIC RAILWAY BILL.—This Bill and several other Metropolitan Railway Bills are to be considered by a select committee, consisting of Sir Joseph Bailey (chairman), Mr. W. Nicholson, Mr. E. Noel, and Mr. Rankin. The committee will not meet until the end of the present month.

DEATH FROM LIGHTNING.—A heavy thunderstorm, accompanied by vivid lightning, burst over Cheshire and Flintshire on the night of the 4th inst. At Connah's Quay, near Chester, John Jones, a pilot, was walking through Messrs. Ferguson and Baird's shipbuilding yard, when he was struck by lightning and killed instantaneously.

UNITED TELEPHONE COMPANY.—This company notify that their offices, call rooms, and telephone exchanges will be closed to-day, the 12th inst., as well as Easter Monday (Bank Holiday), for the purpose of making certain additions and alterations which the recent rapid development of the company's system has rendered imperative.

PROVINCIAL TELEPHONE COMPANY.—At an extraordinary meeting of this company, held at the offices, 11, Queen Victoria-street, E.C., recently it was resolved to wind up the company voluntarily. The creditors are to send their names and addresses with particulars of their claims to Mr. W. B. Campbell, 11, Queen Victoria-street, E.C., by May 2.

SUBMARINE CABLES TRUST.—We are requested to state that the coupons of the Submarine Cables Trust due on the 15th inst. will be paid on and after that date by Messrs. Glyn, Mills, and Co., at 67, Lombard-street, E.C., between the hours of 11 a.m. and 2 p.m. The coupons must be left for examination three days previous to calling for payment.

CUBA SUBMARINE COMPANY.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during the month of March was 3,857, estimated to produce £3,200, against 5,139 messages, producing £4,609 in the corresponding month of last year. The traffic receipts for the month of December, estimated at £2,500, realised £2,559.

ELECTRIC LIGHTING IN VIENNA.—The *Standard's* Vienna correspondent, telegraphing on Tuesday night, said:—"The Emperor, accompanied by the Crown Prince, this afternoon paid a visit to the Ornithological Exhibition, which is now every day attracting thousands of sightseers both in the day time and in the evening, when the halls are illuminated by the electric light."

SIXPENNY TELEGRAMS.—According to a statement made by Mr. Fawcett in the House of Commons last week, the time for the reduction of the rates of inland telegrams would be announced by the Chancellor of the Exchequer in his Budget speech. In some quarters it still seems to be supposed that the alteration will take place next October, but this we believe is highly improbable.

INDO-EUROPEAN TELEGRAPH COMPANY.—The board of directors of this company have determined, subject to audit, and after setting aside £5,000 to the reserve fund, to recommend the payment for the six months ending the 31st December, 1883, of 17s. 6d, per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 10s. per share, carrying forward £59 to the next account.

ELECTRIC LIGHTING IN CANADA.—A company, under the title of the Royal Electric Company, has purchased the patents and rights of the Thomson-Houston system, so far as the Dominion of Canada is concerned, from the American Electric and Illuminating Company. The latter company had erected a factory for the manufacture of the necessary apparatus for working the above system in Montreal, and had carried out several installations of electric lighting.

ANGLO-AMERICAN TELEGRAPH COMPANY.—At a meeting of the directors of this company, held on Friday, the 4th inst., it was resolved, after placing the quarterly sum of £37,500 to the credit of the renewal fund, to declare an interim dividend for the quarter ending 31st March, 1884, of 12s. 6d. per cent on the ordinary stock, and 25s. per cent. on the preferred stock, payable on the 1st May to the stockholders registered on the books of the company on the 31st March, 1884.

NEW CABLE.—The Swedish Government has given notice that a telegraph cable has been laid from a position on the eastern side of East Kruthusholm (King's Holm, in communition by cable with Carlskrona) to a position on the western side of Basareholm, Carlskrona Harbour. The shore ends of both cables are marked by poles about 20ft. high, and surmounted by a red cross, under which there is a large white notice, with Telegraf-Kabel in black letters on it. Mariners are cautioned not to anchor in the vicinity.

THE ELECTRIC RAILWAY AT BRIGHTON.—The first journeys were made on Friday afternoon, last week, on the electric railway, about a mile long, which, with the sanction of the town council, has just been extended at the edge of the Brighton beach, starting opposite the entrance to the Aquarium, and running eastward beyond the chain pier. There is a single ornamental car, which will hold about a dozen persons, and the speed is limited to six or eight miles an hour, though a much higher rate can be attained. The experiment was entirely successful.

EASTERN TELEGRAPH COMPANY.—This company announce the payment on the 15th inst. of a dividend of 3s. per share on their preference shares, less income-tax, for the quarter ending March 31, 1884, and also that an interim dividend of 2s. 6d. per share on the ordinary shares, free of income-tax, in respect of profits for the quarter ended December, 31, 1883, will be paid on the same date. The traffic receipts of this company for the month of March, 1884, amounted to £67,285, and to £49,529 in the corresponding period of 1883, being an increase of £17,756. This large increase is partly owing to the fact that the Easter holidays fell in March last year.

INTERNATIONAL CONVENTION OF PATENTS.—In the House of Commons, on the 3rd inst., Lord E. Fitzmaurice, replying to Mr. Samuelson, said, "The acceptance of the British accession to the International Convention on Patents, which accession was communicated to the French Government on the 17th ult., has not yet been reported by Her Majesty's ambassador; but when it is received the Convention, together with the British Declaration of Accession, will be presented in the usual course to Parliament. I think that the correspondence with our Colonies and with foreign Powers can be laid on the table, but it will be necessary to consult the departments more particularly concerned. The only foreign correspondence is with the French Government, who have carried on the negotiations."

CITY AND GUILDS INSTITUTE.—The examinations in technology in connection with this institute will take place at the different provincial centres throughout the United Kingdom on Wednesday, May 28, at 7 p.m. Secretaries should send in returns of candidates who wish to be examined by Monday, April 28, after which date no application can be received. Individual candidates, who are unable to arrange to be examined at a provincial science centre, can, on application to the director and secretary, be examined in London, at the Finsbury Technical College, Tabernacle-row, E.C. The examination will be held in forty-five subjects. A programme containing syllabus of each subject and last year's examination questions can be obtained from the central office of the institute, Gresham College, London, E.C.

SUPPOSED ACCIDENT FROM ELECTRIC LIGHTING.—From New York it is reported that last week the "Rebecca Everingham," a river steamer which was laden with cotton, and had forty-one persons on board, passengers and crew, had been totally destroyed by fire near the town of Florence, in the State of Georgia. The disaster is attributed to a fragment of the carbon of the electric light falling upon the cotton. Eleven deaths are known to have taken place, and it is feared that that number will be raised to twenty. The entire living freight of the vessel would have been sacrificed but for the splendid heroism of the pilot, who ordered his son to swim to the shore with a rope, and at the same time continued to steer the vessel towards the shore with the flames literally surging around him. By these means about half the number on board were saved.

TELEGRAPHIC CHARGES IN VICTORIA.—Mr. W. Madden, M.L.A., has introduced to Mr. Berry a deputation from the residents of Nhill and North Lillimur to ask that the charge for telegrams from the latter place to Border Town, in South Australia, might be reduced from 2s. to 1s. per dozen words. Mr. Madden stated, says the *Colonies and India*, that the deputation desired Mr. Berry to make similar arrangements with the South Australian Government to those which existed between New South Wales and Victoria, whereby telegrams between Wodonga and Albury were charged at the rate of 1s. per dozen words only. Mr. Berry pointed out that the circumstances were altogether different. Albury was only three miles from Wodonga, whilst North Lillimur was fully fourteen miles from Border Town. He promised, however, to communicate with the South Australian Government on the question.

ELECTRIC LIGHT FOR COLLIERIES.—The surface works of the Gouffre colliery, at Châtelineau, near Charleroi, extending

Digitized by Google

for 275 metres along the river Sambre, and covering about five acres of ground, are illuminated by six Brush lamps of 2,000 candles each, placed at a height of 10 metres, or nearly 33 feet. The light is sufficient for eighteen screens, and also for the shunting operations over the whole space. The lamps are arranged in single circuit, formed by a cable of seven conductors, and the Brush dynamo is made to revolve at 900 or 950 a minute, by means of gear and a single-cylinder vertical engine, provided with a Tangye governor. The total cost of the plant was 5,871,025fr. (£234,841), and the expense of lighting is 500fr. (£20) a month, or half what it was before with lanterns and braziers. As there is plenty of power to spare, it is proposed to run a larger dynamo, and increase the number of lamps to ten.

THE PILSEN DYNAMO.—The Pilsen-Joel and General Electrical Light Company, who have so largely introduced the Pilsen dynamo electric machine into this country, have now, in response to the steadily increasing demand for incandescent lighting, produced another type of this machine specially adapted to this purpose. The company's new machines have several novel features, both in the arrangement of iron in the armature core and in the method of winding adopted to secure currents of great quantity for subdivision. These types of machines, though giving widely different volumes of current, are almost identical in appearance. The machines are all made under the superintendence of the company's electrical staff, at their factories, Malden-crescent, Kentish Town, the company's latest contracts being the lighting of the Armoury of the Tower of London, of the Bethnal Green Museum, for the Science and Art Department, and the new Tilbury Docks for the contractors. We also understand that the company is now busily engaged in fitting up the electric light on board a new steamship.

IMPROVEMENTS IN LECLANCHE'S BATTERY.—The Leclanché Battery Company, of No. 149, West 18th-street, New York, have introduced a new form of jar and cover for the well-known prism battery. The cover rests upon a shoulder inside of the jar, which is oval in shape, the rim of the jar above the cover being concave in shape. The cover when in place closes the jar sufficiently tight for ordinary purposes; but, if desired, it may be hermetically sealed by pouring on the cover melted wax, which will spread over the cover, run into the concavity of the rim, and be held firmly in place, thereby effectually sealing the jar. Any kind of wax may be used for the purpose, but paraffin is preferable on account of the ease with which it can be removed. The cell can be unsealed with an ordinary pocket knife whenever necessary to renew or clean it. The latter process, however, will scarcely be necessary, as the paraffin prevents the salts from climbing up and fouling the cover. A cell thus sealed can be transported on boats, cars, and other vehicles without danger of slopping over the liquid.

NOT PAYING FOR YOUR WHISTLE.—A short time ago the *Pall Mall Gazette* gave a description of the new regulation whistle supplied to the police, and stated—probably half in jest—that by inquiring at their office, through the telephone, anybody could hear the sound of the said whistle. A week later the *Pall Mall* reports that the experiment of inviting subscribers of the United Telephonic Exchange to communicate with the telephonic chamber of the *Pall Mall Gazette*, No. 2,732, if they wished to hear the peculiar note of the new police whistle, has proved signally successful. "Our invitation was so generally complied with that we had to appoint the broadest chested of our staff as Whistler in Attendance, and for the last six days he has been kept constantly employed sounding the whistle, which has now been heard in all parts of London. Consideration for the health of our official whistler, now exhausted by incessant duty, compels us to notify that after to-day the whistle will be banished from our telephonic chamber, and those who wish to hear it must apply to Scotland-yard."

TELEPHONE COMPANIES AND THE PUBLIC.—In the City of London Court, on Monday last, before Mr. Harrison, Deputy-Judge, an action was brought by Messrs. Sercombe and Son, wine merchants, 71, Fleet-street, to recover from the London and Globe Telephone and Maintenance Company compensation in damages for trespass on the roof of their business premises. —Mr. M'Intyre was counsel for the plaintiffs, and stated that the case was one of considerable public importance. The defendant company had asked leave to put up wires on the roof in question. Permission was refused, on public and other grounds; but, notwithstanding, certain wires were fixed on poles, in the doing of which the roof was damaged. In fact, the company's men were at work at intervals for eight or nine months, creating no small annoyance.—His Honour: Why did your clients not take the company before a magistrate?—Mr. M'Intyre: I don't know; but they now seek redress here, the roof having been nearly destroyed.—Several witnesses were examined to prove the damage, and correspondence was put in showing that the company denied liability.—His Honour, however, found for the plaintiffs, with costs.

SURVEYORS' CLERKS IN THE POST OFFICE.—In the House of Commons on 4th inst., Mr. O'Brien asked the Postmaster-General if it were a fact that not fewer than fifteen in the second class of surveyors' clerks in the Post Office, or nearly one-half, were sons or relatives of surveyors or officers holding high positions in the Post Office; and whether, seeing that the surveyors exercised control over postmasters and others, and that those appointments carry with them a salary commencing at £150 a year, and rising through two classes to £800 a year, in addition to allowances of 15s. a day and upwards, some means could be devised for throwing open these appointments practically, as well as nominally, to the whole service.—Mr. Fawcett: Some time before the hon. member placed his question on the paper I had notice of the facts to which he now refers, and which, in the main, are correct. I have come to the conclusion that it is desirable that some course should be adopted by which persons in the service should have readier access to the surveyors' staff. I have not been able to come to a decision as to the best plan to adopt; but I can assure the hon. member that there will be no unnecessary delay.

INVISIBLE WIRE.—Platinum wire has been drawn down so fine by Mr. H. F. Read, of Brooklyn, New York, as to be invisible to the naked eye, although, says the *Scientific American*, its presence upon a perfectly white card could be detected by the touch, and could be seen with the aid of a small magnifying glass when the card was held in such a position that the wire cast a shadow. A small platinum wire, about No. 18, was enclosed in a close-fitting tube of silver. The tube was made by taking a long and narrow sheet of silver, about one-twentieth of an inch thick, folding it over into a cylinder, and drawing down until the wire would just fit in it. This was then drawn down until the tube containing the wire was only as large as the original wire. A short length of this was cut off and encased in a second tube of silver, which was drawn down in the same way. This operation was repeated until the platinum wire had been reduced sufficiently in diameter. The last wire was drawn as fine as the dies would permit,

Digitized by Google

when the silver coating was removed by an acid. During the work it was necessary occasionally to anneal the wire. The resulting wire was in short lengths and had no strength. It was designed to be used for the cross wires in telescopes, its perfect opaqueness and fineness rendering it particularly applicable, but its extreme weakness made its handling almost an impossibility.

ELECTRIC LIGHTING FOR LIGHTHOUSES.—Our American cousins are making experiments with the electric light as an illuminant for lighthouses, and a large lighthouse with a light of the first order has been erected at the Lighthouse Department Depot, Tompkinsville, S.I., to test its practicability. "General Duane, in charge of the lighthouse station at Tompkinsville, says that when the new light is put in operation experts will be sent to a point on Long Island equidistant from the Tompkinsville electric light and the Highlands light. Both of these lights are of the first order, or the largest made. The Highlands light burns oil. The experts will determine which light is the better for penetration of distance and for distinctness. Electricity would cost, it is said, ten times as much as oil, because duplicates would be necessary of all the apparatus, while the supplies of coal, water, and needed articles would require double supply service, owing to the isolated position of lighthouses." We may point out that while one or two of our lighthouses have been lighted by electric lights for many years, yet we are only just making systematic experiments to test the value of gas, oil, and electricity for this particular kind of lighting. It is to be noted also that France has decided to adopt the electric light in forty or more lighthouses, and that several of these have been fitted with the new light within the past year or so.

ELECTRIC LIGHTING ON H.M.S. "RAINBOW."—During the last few days H.M.S. "Rainbow," the head-quarters of the Royal Naval Artillery Volunteers in London, has been the scene of considerable gaiety on the occasion of a series of theatrical performances given by the members of the corps. As last year, so on this occasion the old boat was lighted by electric lamps, which are allowed on all hands to be a vast improvement on oil lamps. The programme was a long one, and comprised *The Area Belle*, a well known farce, *Withered Leaves*, a comedietta, and an original burlesque called *Fancyland; or, the Ideal King*, in one act, by Mr. Charles F. Fuller, a member of the corps. This latter was the event of the evening. It is hardly within our province to go into dramatic details, but we may say that politics were prominent in Mr. Fuller's burlesque, and that one of the chief characters was a certain Grandolman, nicknamed "The Shuffler," Prime Minister to King Gorgonzola. The entertainments got up by the corps are always carried out with spirit, and the present was no exception to the rule. Forty-seven 10 candle-power Swan incandescent lamps were used, requiring an E.M.F. of 14 volts. The current was supplied by 15 double Holmes primary cells, and we were told that they ran for two days without charging. The whole of the installation was carried out by Mr. Wharton, of the firm of Laing, Wharton, and Down, of Holborn-viaduct, E.C., a member of the corps, and was in every way a success.

SULPHURIC ACID.—To test sulphuric acid for the purpose of ascertaining if it is pure, the *Oil and Colourman's Journal*, an American paper, suggests the following methods:—"A small portion of the sulphuric acid is evaporated on a platinum sheet, which is subsequently brought to a red heat. Good sulphuric acid should not leave any residue; if there is any, it is generally sulphate of potash, or soda, or even lead. These are derived from the manufacture, and cannot be classed among adulterations. We may say here that on account of the cheapness of the sulphuric acid it never is wilfully adulterated, but may contain many foreign ingredients. A little sulphuric acid is diluted with water and a few drops of concentrated muriatic acid added; if the solution, which was clear before, becomes milky, it indicates the presence of lead, which can be more safely identified by letting a current of sulphuretted hydrogen gas pass through the liquor. Another ingredient which is often found in sulphuric acid, particularly such products as are made from pyrites, is arsenic. Arsenic is detected by the so-called Marsh test. If mixed with water and granulated zinc, hydrogen gas is liberated, which should not contain any trace of arsenic. The hydrogen gas is ignited, and the flame allowed to strike a cool porcelain plate, on which, if arsenic is present, metallic arsenic is deposited. Sub-nitric or nitric acid may be detected by throwing a small piece of copperas in the questionable acid. If it shows a brown coloration where it touches the liquid the presence of the above impurities is indicated. Chlorine or muriatic acid is detected by adding a few drops of nitrate of silver into the diluted sulphuric acid; a precipitate or a milky appearance of the mixture shows the presence of chlorine or muriatic acid. Sub-nitric acid, derived from the manufacture, is shown by adding iodide of potash and starch mixture to the sulphuric acid; a blue coloration shows sub-nitric acid."

ELECTRIC LIGHTING IN DUBLIN. — We learn that the Alliance Gas Company has discontinued working the electric light in Dublin on rather short notice—only three days' intimation to that effect being given to those to whom the company was supplying current. We are somewhat surprised at this unexpected course, especially as we are informed the company was doing a fair business for the few months they have been engaged in this kind of work; and, moreover, it appears several orders were coming in for the supply of the new light. A rumour has reached us to the effect that the directors, seeing the probability of electric lighting making rapid headway, became fearful about their gas interests, and as they are doing a flourishing business in this direction they naturally enough view with alarm the encroachment of a new system which would tend to disturb the existing arrangements, and probably seriously affect their present handsome dividends during the transitory period which would necessarily have to be faced for the purpose of supplying the electric light on a large scale. It is also stated as a reason for the discontinuance that the company discovered they were acting illegally in dealing with the electric light; in other words, they had no power under their several Acts of Parliament to spend money on any system of lighting other than gas. Whatever may be the cause, we think the company are bound to make it known, for it certainly is trifling with a great and important industry for a company to intimate its willingness to supply the electric light, and then after a short period, and on such short notice, and without apparent cause, to discontinue the work. We believe by this action on the part of the Gas Company the City of Dublin is again left without a local company dealing in electric lighting; and the only conclusion likely to be arrived at by an uninitiated public is that the electric light is a failure, for first the Brush Company tried it and failed, and subsequently the Gas Company tried it and failed.

HALL'S PHENOMENON IN LIQUIDS.—Herr Anton Roiti investigated this subject, and contributed the results of his experiments to Exner's "Repertorium der Physik." The following abstract is taken from "Abstracts of Papers in Foreign Transactions," published by the Institution of Civil Engineers:—"Hall has shown that when a current is passed through a thin plate of metal there is a transverse electromotive force

Digitized by Google

induced in the plate if it is placed with its plane perpendicular to the lines of force of a magnetic field. This is the phenomenon suggested as possible by Maxwell, and expressed by the assumption of a 'rotatory coefficient' in the equations of conduction. Hall has determined this coefficient for various metals. The author first experimented with a sheet of silver electrolytically deposited on glass, and in general verified Hall's results. The experiment was then tried in a different way. The main current was passed through a silver wire, A B, 0·03 millimetre in diameter, and about 4 centimetres long, held by two stout copper wires. At right angles to this was a second similar silver wire, C D, forming a cross with the first. This second wire was stretched by two suspended weights, and had stout copper wires similarly attached to it. The plane of the wires was at right angles to the lines of magnetic force, their point of intersection being in the axis of the electro-magnets. The copper terminals of C D were connected with an exceedingly sensitive galvanometer. It was found that if the tension of the wire was considerable no effect whatever could be observed when the direction of the field was reversed, even with a primary current produced by six Daniells. This shows that the supposition of a direct effect upon the current is not admissible, and that the phenomenon really depends upon a change in the specific resistance, in the manner considered by Maxwell. In experimenting on liquids the author found that the polarisation introduced considerable difficulties, but he concludes, from experiments with sulphate of zinc solution, that if the concentration of the solution is less than that of maximum electrical conductivity (specific gravity 1·286) the electro-dynamic action produces an increase in the conductivity of the liquid in the direction of C D, and conversely if the concentration is greater than that of maximum conductivity."

Electrical Engineering at the German Polytechnic Schools.—At the present time, when the City Guilds and Livery Companies have taken technical education under their fostering care, it may not be uninteresting to note what our Continental neighbours do for the training of electrical engineers. We gather from an exhaustive article on this subject, which lately appeared in the *Austrian Railway and Steamship Gazette*, that those men who are best able to judge are not altogether satisfied with the means adopted by the German Polytechnic Schools for teaching the rising generation how to become electrical engineers. In December, 1881, Dr. Werner Siemens, speaking at a meeting of the German Electrical Society at Berlin, said that "it would be very desirable to promote the general knowledge of electrical science. In all technical colleges professorships for electrical engineering ought to be established in order to make the rising generation of engineers familiar with the practical applications of electricity. With our increased knowledge of the subject the aversion which many yet feel towards the introduction of electrical appliances will gradually diminish, and a host of prejudices at present widely spread will altogether vanish." Technical Colleges and Polytechnic Schools in Germany seem to have taken these words to heart, and to have gradually begun to admit the new science, but not exactly in the manner intended by Dr. Siemens. Such, at least, must be the inference drawn from a later speech of his before the same assembly in January, 1884, when he said, "The impulse I then gave has in many cases been misunderstood, as if I had advocated the establishment of professorships for the purpose of educating a special class of engineers, viz., electrical engineers (*elektrotechniker*), there has already been a large concourse of young men to this 'new branch,' and this is to be regretted. Electrical engineering is not an independent branch of science, but simply an auxiliary to many other branches. It should be so taught as to enable the young engineer to apply it where possible to the improvement of his special branch of engineering. The manufacture of electrical machines and appliances is simply a branch of general mechanical engineering, but not an independent profession." Although we in this country are generally in the habit of specialising professions and trades much more than is customary in Germany, most thinking men who are interested in technical education will probably agree with Dr. Siemens as far as concerns the training of students. Young men who wish to "go in for electricity," or, at any rate, who wish to make heavy electrical engineering their profession, should become thorough mechanical engineers first and electricians afterwards.

Sir John Bennett on Exhibitions.—At the Whitfield Tabernacle, Tottenham Court-road, recently, Sir John Bennett gave an address on "Electric Exhibitions at Home and Abroad." The lecturer said that he proposed to say something about electric exhibitions at home and abroad, but should refer to the Paris Exhibition, which was the first great display before the world by practical men to show the present position and future prospects and capacities of the mysterious electric current. He had known Paris all his life, and so when the Electric Exhibition took place he went prepared to see a display such as the French only can accomplish—their taste, their science, their ingenuity, and acquaintance with effect—you found all these evinced in their Palace of Industry. They were going to show the world what men knew of the nature, and character, and capacities of the electric current. And they did it well, too. He had heard of electricity as a scholar in his early days; he remembered fifty years ago a very interesting lecture being given at Greenwich on electricity by a Quaker. He had a glass disc and silk and sealing wax, but he produced sparks by friction; and he did something more, for about the hall he had coils of wire, and he started the current at one end and instantaneously a spark appeared at the other end. There was the telegraphic action of the current fifty years ago. But we had to wait for its further development. This telegraphic power soon came to the notice of the postal authorities, and was utilised by them, but in the meantime electricity had been applied to other matters, and these were shown at the Paris Exhibition. The French have a happy knack of treating scientific subjects in an artistic way, and their building was not only a temple of knowledge, but also a work of art, divided into compartments, each showing some illustration of telegraphic power by various exhibitors. They took visitors to the exhibition by electricity, which never once failed as a motive power, and at the building they had numerous facilities for ascertaining the nature of the current. Speaking of the electric light, Sir John Bennett said that what was now wanted was to bring this illuminating agency into our streets and by ways for domestic purposes. All the best men and the best philosophers throughout the world know perfectly well the value of this discovery, and so there is a chance of our coming into possession of its benefits. Even now we have a clumsy way of applying it for illuminating purposes. At present it is brought through a wire, but we don't know that a wire will be necessary in the future. In concluding his address he expressed a hope that ere long the electric light would be more universal, because of the small cost with which it would be supplied, and that it would be extended and be made, not the property of the few, but utilised for the blessing and contribute to the happiness and prosperity of the whole human race.

## ELECTRO-CHEMISTRY.—INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 487.)

**Elimination of Impurities from Copper by means of Electrolysis.**—Very few metals are likely to be electro deposited along with copper from the usual acid sulphate depositing solution by a separate current; the most likely one is cadmium. In the electrolysis of that solution with an anode of ordinary copper, a considerable amount of black insoluble matter separates at the anode. An analysis of this substance by Max Duke of Leuchtenberg gave the following:—

| | | |
|---|---|---|
| Tin | 33·50 | |
| Oxygen | 24·82 | |
| Copper | 9·24 | |
| Antimony | 9·22 | |
| Arsenic | 7·20 | |
| Silver | 4·45 | |
| Sulphur | 2·46 | |
| Nickel | 2·26 | |
| Silica | 1·90 | |
| Selenium | 1·27 | |
| Gold | ·98 | |
| Cobalt | ·86 | |
| Vanadium | ·64 | |
| Platinum | ·44 | |
| Iron | ·30 | |
| Lead | ·15 | = 99·69 |

(Erdmann, *Jour. Pr. Chem.*, Vol. XLV., pp. 460—468.)

The following are comparatively recent analyses kindly supplied to me by a friend. They are those of the powder from copper plates used as anodes in depositing copper statues, &c.:—

| No. I. | | No. II. | | No. III. | |
|---|---|---|---|---|---|
| Copper | 85·850 | Lead | 27·70 | Copper | 67·90 |
| Water and oxygen | 4·950 | Water and oxygen | 21·05 | Sulphur | 18·10 |
| Arsenic | 2·480 | Copper | 19·40 | Iron | 5·55 |
| Silver | 1·815 | Antimony | 7·35 | Insoluble earthy matter | 3·40 |
| Sulphuric acid. | 1·150 | Sulphur | 6·35 | Organic matter. | 2·25 |
| Insoluble earthy matter | ·950 | Silver | 5·61 | Lead | 2·05 |
| Antimony | ·750 | Arsenic | 5·20 | Silver | ·55 |
| Iron | ·750 | Earthy matter. | 4·35 | Loss | ·20 |
| Bismuth | ·650 | Bismuth | 1·25 | | |
| Alumina | ·250 | Chlorine | ·70 | | |
| Chlorine | ·250 | Iron | ·60 | | |
| Gold | ·085 | Nickel | ·20 | | |
| Lead | ·050 | Organic matter | ·20 | | |
| Loss | ·020 | Gold | ·01 | | |
| | | Loss | ·03 | | |
| | 100·000 | | 100·00 | | 100·00 |

**Refining of Crude Copper by Electrolysis.**—This process is carried out on a large scale by Messrs. Elkington, at their copper works, Pembrey, South Wales. The process simply consists in making large slabs of the crude metal, obtained by the ordinary smelting process, anodes in the usual cupric sulphate solution, and passing currents from numerous dynamo electric machines through the solutions, until the slabs are wholly dissolved and their copper deposited. Each current passes in an undivided state through a series of such electrodes and solutions in order to diminish the cost of the process.

The impurities which separate vary, of course, with the different samples of crude metal. In the process, oxygen, sulphur, selenium, carbon, boron, silicon, and arsenic are not deposited at the cathode. Silver is precipitated at the anode by the traces of hydrochloric acid present in the common sulphuric acid employed. Gold falls as metal at the anode, lead as sulphate; carbon and metallic sulphides, also selenium and silica, fall at the anode. Zinc, iron, tin, cadmium, cobalt, nickel, and antimony are more or less dissolved, but, being less readily deposited than copper, remain in solution. Arsenic falls as an arsenide, and the metal most likely to be deposited, viz., cadmium, is present so rarely, or in so small an amount, as to remain in solution.

**Electric Etching, &c.**—Copper being a very suitable metal for the purposes of engravers and printers, the electric corrosion of anodes in a solution of cupric sulphate was soon applied to engraving and etching. Copper being also a metal easily deposited, the process of electro-deposition of copper in solutions of its sulphate was also applied to the multiplication of engraved plates, the copying of set-up type, the manufacture of works of art, and even of colossal statues, &c. The details of these and other technical uses of electro-chemical action may be found described in works on Electro-Metallurgy.

For the uses of electrolysis in the metallurgy of copper by the processes of Becquerel, Keith, and Patera, see *Jour. Chem. Soc.*, Vol. XXXVI., 1879, p. 760. Also Blas and Miest, *Chem. News*, Vol. XLVI., p. 121. The latter also apply electrolysis to all kinds of ores.

**Electrolysis of Cuproso Potassic Cyanide.**—There are several cuproso cyanides of potassium. The one usually employed for electro-deposition is formed by dissolving green cuproso cupric cyanide to the point of saturation in a solution of potassic cyanide, and then adding some more of the potassic solution, and using the mixture at a temperature of about 150° F. The base metals much less readily deposit copper by simple immersion in this liquid than in the ordinary cupric sulphate solution. By the passage of a separate current this salt is also less readily decomposed than cupric sulphate, and hydrogen is freely set free at the cathode along with the copper.

Various mixtures of salts containing potassic cyanide have been employed for depositing copper upon base metals. Roseleur recommends the following:—Rub 20 parts of crystallised verdigris to powder in a little water, add to it with stirring 20 parts of washing soda dissolved in 200 parts of water, mix the solution with one of 20 parts of bi-sulphite of sodium dissolved in 200 parts of water, and add the mixture with stirring to a solution of 20 parts of pure potassic cyanide dissolved in 600 parts of water; then if the mixture is not colourless, add more potassic cyanide until it is so. It may be used either hot or cold. A second one he recommends is composed of 20 parts of strong aqueous ammonia, 30 of sodic bi-sulphite, 35 of cupric acetate, 50 of potassic cyanide of 70 per cent., and 2,500 of water. The ammonia and copper salt are dissolved in one portion of the water, and the cyanide and bi-sulphite in the other, and the two solutions mixed. If the resulting solution is at all blue, more potassic cyanide must be added to render it colourless. This mixture also may be used hot or cold.

Another liquid employed for the same purpose may be made by dissolving 40 parts of the blue ammoniuret of copper and 80 parts of potassic cyanide in about 1,000 parts of water. W. H. Walenn recommends cyanide of copper dissolved to saturation in an aqueous solution of equal parts of potassic cyanide and ammonium tartrate, and sufficient oxide and ammoniuret of copper added to prevent evolution of hydrogen at the cathode when the liquid is used at 80° C. with a current from a single Smee's element. Dr. Elsner used a solution composed of one part of potassic bitartrate boiled in 10 parts of water, and as much freshly-prepared and wet hydrated cupric carbonate which has been washed with *cold* water, stirred with it, as the liquid will dissolve. A small quantity of potassic carbonate is then added. He states that a copper anode dissolves readily in this mixture.

According to F. Weil, by employing an alkaline solution in which cyanides are re-placed by organic acids or glycerol, copper may be firmly deposited by a separate current on wrought iron, cast iron, and steel, and the acids or glycerol are not decomposed (*Jour. Chem. Soc.*, Vol. XLII., 1882, p. 670).

Copper has been deposited upon iron by the combined action of simple immersion and of a separate current in a solution of one part of cupric oxalate and a large excess of potassic bi-or-quad-oxalate in ten to fifteen parts of water (Watts's "Dictionary of Chemistry," Vol. VIII., Part 2, p. 1,118).

The physical properties of the copper deposited from the various mixtures, and from each solution at different temperatures, or by different strengths of current, vary considerably. A trace of carbonic bisulphide in the cupric sulphate solution makes the deposit brittle, the anode also becomes black, but if there is also a great excess of acid, it sometimes becomes very bright; and if the liquid also contains much potassic sulphate, the deposited copper is said to be bright. The deposit also from the cyanide is usually bright when the current is strong, and of a dull aspect when it is weak. According to Favre,

Digitized by Google

electro-deposited copper contains more heat than the rolled metal (Watts's "Dictionary of Chemistry," Vol. VII., p. 462). For the absorption of gases by deposited copper, see Watts's "Dictionary of Chemistry," Vol. VII., p. 383.

(TO BE CONTINUED.)

## NEW STANDARD UNIT OF LIGHT.

In the January number of the *Electrotechnische Zeitschrift*, F. v. Hefner-Alteneck suggests a new standard light for photometric work, which by reason of its simplicity and constancy would appear to supply a very widely-felt want in this direction.

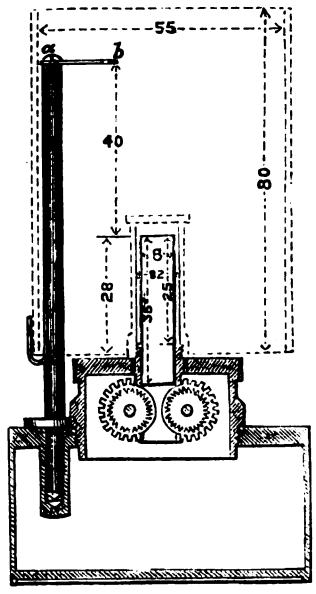

FIG. 1.

The new unit is an open flame from a wick saturated with amyl-acetate. The wick consists of cotton fibre, completely filling a tube of German silver one inch long and of 316 mils. internal and 324 mils. external diameter; the length of the flame, measured from its top point to the edge of the tube, being 1·58 inch. This standard flame should be lighted at least ten minutes before it is required for use. Fig. 1 shows a sectional elevation, and Fig. 2 the plan of a standard lamp, the

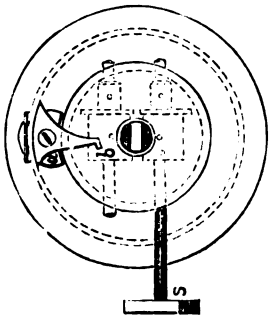

FIG. 2.

dimensions being given in millimetres. The length of the flame is regulated by raising or lowering the wick by means of the knob S, and it must be adjusted so that the highest point of the flame is in line with the index *b*. To provide against disturbance of the flame through air currents a wide cylindrical glass chimney (shown in dotted lines) may be employed, but an allowance of 2 per cent. for loss of illuminating power through absorption of light by the glass must in this case be made. The author finds that so called standard candles vary as much as 10 per cent., but by taking an average from a large number of observations, he found the above dimensions for his lamp, the light from which is equal to that which the usual English standard candle ought to give. A question of importance is in how far the value of the standard is altered by employing various fuels or by inaccuracies in the construction and treatment of the lamp. As regards the fuel only perfectly viscous liquids and only those burning with a clear, smokeless flame could be used. The following table gives some of the results obtained with flame of standard size:—

| Kind of fuel. | Formula. | Percentage of weight of carbon. | Boiling Point, centigrade. | Illuminating power. | No. of seconds required to burn 1 gramme. | In 100 seconds burnt grammes carbon. |
|---|---|---|---|---|---|---|
| Amyl-Valerate ..... | $C_{10}$ $H_{20}$ $O_2$ | 69·7 | 195 | 1·03 | 430 | 0·162 |
| Amyl-Acetate ..... | $C_7$ $H_{14}$ $O_2$ | 64·6 | 138 | 1·00 | 388 | 0·166 |
| ,, ,, comm.... | — | — | — | 1·00 | — | — |
| Amyl-Formiate..... | $C_6$ $H_{12}$ $O_2$ | 62·1 | 122 | 1·01 | 372 | 0·163 |
| Isobutyl-Acetate ..... | $C_6$ $H_{12}$ $O_2$ | 62·1 | 116 | 0·99 | 373 | 0·163 |
| Isobutyl-Formiate ... | $C_5$ $H_{10}$ $O_2$ | 58·8 | 98 | 0·97 | 355 | 0·166 |
| Aethyl-Acetate ..... | $C_4$ $H_8$ $O_2$ | 54·5 | 75 | 0·24 | 312 | 0·258 |

It will be seen that, with the exception of aethyl-acetate, these liquids are of nearly the same illuminating power, and that the quantity of carbon consumed in a given time is likewise almost identical. But not all are equally suitable from a practical point of view. The boiling temperature of amyl-alverate is too high, and the formiates seemed to attack somewhat the brass parts of the lamp. The best fuel seems to be amyl-acetate, which is not only procurable anywhere, but is also sufficiently cheap, costing only about 5s. per kilogramme if chemically pure, and 2s. 6d. if commercially pure.

In all observations the flame was adjusted to the standard length, and no attempt was made to regulate it so as to burn a definite weight of fuel in a given time, the author having found that the length of flame, rather than quantity of fuel, determines its illuminating power.

The lamp was standardised by the aid of two standard candles and a paraffin lamp. Repeated observations were made, during which it was found that the length of the standard flame had to be varied between 39 and 41 millimetres, so as to bring it to agree with these three standards. As a fair average, a flame of 40 millimetres length was therefore taken to represent one English standard candle.

The author then prepared 12 new standard lamps, and compared them amongst each other to ascertain in how far certain deviations from the rules he had laid down for a correct standard lamp would influence the illuminating power. Neither the substitution of commercial amyl-acetate for that chemically pure, nor the employment of a wick composed of cotton threads instead of loose cotton fibre, altered the illuminating power; but when the wick, instead of being trimmed square and flush with the top of the tube, was allowed to project with a slightly-rounded end, the light was increased by 0·6 per cent. In conclusion, the author thinks that such variations in the construction and treatment of the lamp as are unavoidable in practical use, even with a reasonable amount of care, affect the illuminating power so slightly that the eye cannot detect the difference, and he recommends his new lamp as the most reliable standard which at present is obtainable.

## LIGHTNING CONDUCTORS, ON THE MELSENS SYSTEM.

"*Eripuit cœlo fulmen*" was the terse phrase by which the French Academy characterised Franklin's great discovery; and it may be said that, although many patents have been taken out, nothing really new in protection from lightning has since been invented. There have only been various applications of the principle then laid down, many of them erroneous, some simply useless, but others positively mischievous. In England the protection of buildings from lightning has been treated too much in an empirical manner, while such and such so-called

Digitized by Google

system has made its way more through the force of "puff" than by its own merit; while bills have been swelled by the use of unnecessarily expensive materials and fancy workmanship that have contributed not a jot to the safety of the structure they were intended to protect.

The two leading systems of lightning conductors were ably defined, as follows, by M. Mascart, Professor of Physics to the College of France, at the Paris Electrical Congress of 1881:—

1. The Gay-Lussac system, based on the use of a small number of conductors of considerable sectional area and rods of great height; and

2. The Melsens system, which consists in surrounding the edifice to be protected with a kind of metallic cage, formed by many conductors of small sectional area, and provided with short but numerous rods or points.

The reason why lightning conductors have hitherto been mounted so high above the edifices they are intended to protect is probably because most of the formulæ for giving the zone of protection have been based upon the height: therefore, the greater the height the greater the supposed zone of protection. But it is a remarkable fact that the zone of protection admitted in the famous instructions of the French Academy, drawn up by Gay-Lussac in 1823, has, according to the opinion of scientific men, continued to decrease, until at the present time it has dwindled down to nearly one-fiftieth of what was then considered admissible. It will be seen by the annexed diagram (Fig. 1) of the various zones of protection admitted by the leading authorities, that taking as unity the capacity of the zone given by Gay-Lussac in 1823, that of the various authorities has successively decreased (approximately) to $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{12}$, $\frac{1}{16}$, and $\frac{1}{42}$. M. Melsens is inclined to think that even $\frac{1}{48}$ of the original area cannot be implicitly relied upon. At any rate the transept of the Church of Sainte Croix, at Ixelles-lez-Bruxelles, was injured by lightning on the 3rd July, 1874, within a cone the radius of whose base is $1\frac{1}{4}$ the height of the lightning conductor, which was afterwards found to be in good condition. This is equal to one-fourth the zone originally supposed to be protected; and instances have occurred on board ship of lightning striking the deck, when the lightning conductor on the mast head remained intact.

M. Melsens has adopted as the motto of his system, "*Divide et impera*," and he carries it out by multiplying the terminals, the conductors, and the earth connections. In fact his *paratonnerre* resembles a tree, with branches extending into the air, and roots ramifying in the soil. His terminals are very numerous, and assume the form of an *aigrette* or brush with five or seven points (Fig. 2), the central point being a little higher than the rest, which form with it an angle of 45°. The galvanised iron wires composing them are from six to eight millimetres thick; and the extremities, which may be of copper, are drawn out to sharp points, and should be tinned. The terminals are placed in great number on the more prominent parts of the building. It is now generally admitted that lightning does not strike buildings at a single point, but rather in a sheet. It is obvious that in such a case, or in the event of the globular form being assumed, the brush will constitute a much more effective protection than a single point. The conductors are also numerous, and consist each of a single wire of small sectional area (8 mm. = 0·3inch), so as to be easily laid, and readily follow the contour of a building. The wire should be employed in long continuous lengths, and certainly not in the form of a surveyor's chain, in which there is but slight contact beween the links, and that a very poor one.

While copper may be advantageously employed for the terminals, on account of its resistance to oxidisation, it is not adopted for the conductors, and this for the following reasons:—Its first cost is great; and its high value offers a temptation to theft, which would leave the building in a worse condition than if no lightning conductor had been provided. But more than this, although the conductibility of copper is six or seven times that of iron in the case of a continuous current of slight tension, M. Melsens' experiments show that, for long lengths of small sectional area, iron will conduct as well as copper an instantaneous discharge of high tension. He found that Ohm's law was not applicable in its entirety to sparks of a high tension furnished by charged Leyden jars, frictional electric machines, a Holtz machine, or a large Ruhmkorff coil, in which case the current passes with equal facility through conductors of the same sectional area composed of iron and copper. He has employed bundles or twisted ropes and *aigrettes* of the same shape, composed of different metals, but always obtained the same results. The current was sometimes divided between the two metals, although the portion in the iron seemed generally weaker than that in the copper. The current also passed alternately by one or the other; and a change of direction appeared to exercise no influence on the result of the experiment. There is this difference between the spark produced by the Holtz machine and that of the Ruhmkorff coil. In the former, a single spark passing simultaneously through two conductors, one iron and the other copper, of the same dimensions, generally gives two sparks issuing from their extremities, while in the latter the spark is not divided, but passes sometimes

Digitized by Google

through one and sometimes through the other, even when the length, and consequently the resistance, of the iron is considerably increased. It is true that if Leyden jars, powerfully charged, be discharged through short iron and copper wires, say only a few centimetres long and $\frac{1}{3}$rd of a millimetre in diameter, the iron becomes red-hot and burns, whereas the copper remains intact. But if, on the other hand, copper and iron wires be taken several metres long and $\frac{1}{10}$th of a millimetre in diameter, or finer still, in this case the iron will stand, while the copper is partially melted in the form of a string of beads, or even completely pulverised, and projected to a distance in the state of dust composed of spherical metallic grains, and sometimes in the form of blackish dust, which is oxide of copper. Moreover, practical experience confirms the results ascertained by experiment, as ordinary telegraph line wires must frequently have been struck by lightning; but there is no record of their having been melted. With regard to the division of the current between several conductors, M. Melsens has found by experiment that it will take place between as many as 390 conductors, of conductivity varying from 1 to 6, and of diameters varying from 0·08 mm. to 6·3 mm., the direction of the current exerting no influence

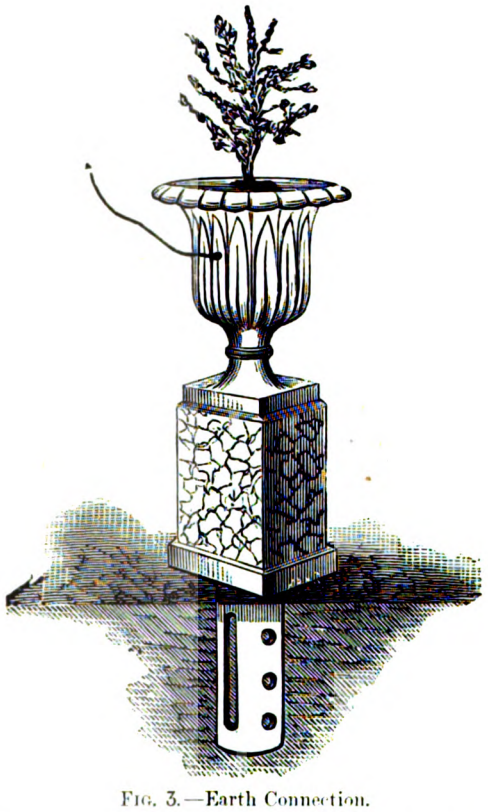

Fig. 3.—Earth Connection.

on the division. He concludes that the spark still becomes divided if, instead of striking the point where the several conductors meet, it strikes only one of them, provided, however, that this one be not too delicate. On placing any one of the 390 wires in contact with gas and water pipes, he could easily detect electrical manifestations in both of them. But the sectional area and conductivity of some of the wires experimented upon could not have allowed to pass more than the $\frac{1}{900}$ or even the $\frac{1}{2300}$ part of the single spark from a large Ruhmkorff coil. Indeed, subsequent experiments showed the remarkably small fraction of $\frac{1}{60000}$. The experiments proved, in addition, that, in the case of homogeneous wires of the same length, when deterioration takes place, it is the same for all; that is to say, it is divided equally among the conductors, or the mechanical energy is the same for all. Moreover, strong sparks from a Leyden jar battery, passing through fine wires stretched so as to be parallel, produced a series of irregular undulations, which were the same in all the wires.

The failure of lightning conductors is generally due to deficient communication with the earth. In order to transmit to water with perfect freedom—that is to say, without any other resistance than what is offered by a good conductor such as iron—the electricity which traverses it, or the lightning which strikes it, a conductor of a square centimetre (0·155 sq. in.) sectional area ought to terminate in a square iron plate, the side of which is 225 metres or 738ft., entirely immersed. Again, to realise the same conditions in damp earth merely, the square plate ought to have a side of not less than 450 metres or 1,476ft. It is evident that these conditions cannot be carried out practically; but in order to reconcile practice as far as possible with theory, it is well to increase, by all the means at disposal, the surface of contact with water or damp soil; to increase the superficial area of the underground portion of the conductor in the pit; and, especially in towns where large buildings are chiefly situated, to connect the conductor with the immense ramifications of the gas and water pipes, and also with warming and ventilation tubes. It is true that M. H. Aerts, manager of the Brussels Gas Works, in a paper before the Society of Belgian Gas Engineers, objected to the connection of lightning conductors with gas-pipes, on the ground that joints were frequently formed of non-conducting substances. But M. Melsens contends that continuity is preserved by the approximate contact of iron with iron, and also by the damp soil surrounding large pipes, and that there is practically nothing to fear on this account; at the same time, such gas pipes should not constitute the only earth contact. It is highly important that the earth connection should be easily accessible to inspection, so as to make sure that, if water, it do not fail, and if earth, it be always damp. In the case

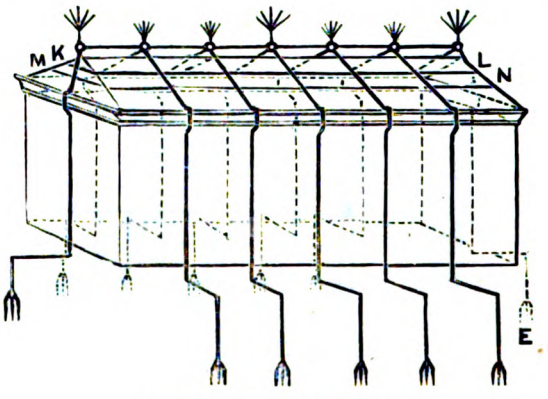

Fig. 4.—Powder Magazine.

of farms and isolated country houses, if the connection be not made with a well or pool, M. Melsens recommends that the conductor terminate in a hollow cylinder of cast iron perforated with holes, projecting above the ground, so as to be always in sight. The upper part may be made into the form of a vase (Fig. 3), so as to receive a plant that requires a great deal of water, when its thriving or otherwise will afford a good indication of the state of the ground below.

The conditions for protecting edifices from the lightning shock have changed considerably since Franklin's discovery. Large masses of iron are now employed in building which it is highly important to place in electrical communication with the conductor. And to this end it is also important that the lightning conductor be taken into consideration in the design of a building, just as are the arrangements for warming and ventilation. This condition has been realised in the case of the new athenæum now being built at Antwerp, in which provision has been made for connecting all the ironwork with the lightning conductor from the very foundations. On the other hand, the want of such foresight is strikingly exemplified in the new Palais de Justice, Brussels, in which there are no less than 9,615 tons of iron. Of this quantity it has been found impossible, except at too great expense, to connect 5,887 tons, or more than half, to the conductors on the Melsens system, connected with numerous brushes on the roof. If the lightning conductor had been taken into consideration in the design, it would have been possible, at comparatively slight expense, to make every particle of metal concur in the

Digitized by Google

system of protection, and, by thus providing innumerable channels by which the electric fluid might reach the common reservoir, to have rendered the building absolutely invulnerable to the lightning shock. Fortunately, however, in the case of the dome (102½ metres = 336 feet high), the point most exposed to be struck, everything was provided for from the commencement; and all the iron in this part of the structure, weighing no less than 3,252 tons, is connected with the conductors and *aigrettes*. The following rule, which is rather more strict than that generally admitted, is laid down by M. Melsens on this subject:—"All parts of metal, if they be of any considerable size, should be placed in communication with the lightning conductor, in such a manner as to form closed metallic circuits, that is to say, by two points, or with connection to two leads at least." At the same time, if the greater portion of the ironwork be electrically connected, so as to realise Faraday's cage, some portion may be left unconnected. This fact has been proved by the following experiment, which M. Melsens lately communicated to the Belgian Academy of Science. On placing a rat, or other small animal in a cage composed entirely of metal, and leaving its body in immediate contact with the wires, a current of sufficient tension to cause instant death may be sent through the cage without affecting its occupant. If the tail be held forcibly outside the cage and in proximity with the opposite pole of the battery, a current sent through the cage will leave the wires where the tail projects, and only affect that organ, just as it will if sent through the tail and out by the cage.

M. Melsens holds, with Gay-Lussac, that lightning conductors for powder mills and magazines need not differ essentially from those for any other kind of building. He does not disapprove of the use of metal in their construction, provided it be all in electrical communication, and be sufficiently connected with water or damp earth. If—which is not likely—there be gas or water pipes in proximity, the conductors should be placed in connection with them. As all the electricity with which a body is charged remains on the outside, the interior, even if electrified by powerful apparatus, is exempt from electrical manifestations, as proved by the most sensitive instruments, and also by Faraday's experiments. M. Melsens therefore advised the director of the Wetteren Powder Mills, covering 24 hectares (nearly 60 acres) of ground, to provide all the buildings with lightning conductors having multiple terminals, leads, and earth connections, and to put all of them in intercommunication, thus constituting one single lightning conductor.

Fig. 4 shows a type of powder magazine most exposed to be struck by lightning. Instead of employing only two conductors of large sectional area, crossing one another over the roof, as recommended by Gay-Lussac, M. Melsens adopts several transverse conductors of small sectional area, crossed by one longitudinal, with *aigrettes* at the intersections, and further connected by belts, K L and M N, consisting of iron wire six to seven millimetres (about ¼ inch) in diameter. This arrangement, which realised the Romas metallic cage, affords a comparatively large number of earth contacts, which may be easily supplemented by a branch leading to a sheet of water or damp soil, either closely adjoining, though sufficiently far from the powder, or at some distance. There is nothing to prevent the magazine, thus protected, from being surrounded by poles surmounted by *aigrettes*, connected by wires crossed in all directions, thus realising a double cage, and affording additional protection. If by any chance the lightning were not arrested by the outer network, it would be hardly likely to penetrate the inner also.

A similar application to telegraph lines, consisting in providing each post with an *aigrette*, connected with the earth, and also with a supplementary wire led above the rest, would probably destroy, or at any rate considerably weaken, the instantaneous or other currents in telegraph wires which so frequently interrupt the service. M. Melsens has so simplified the Marianini rhe-electrometer that it can be made at a cheap rate and easily applied. The indications of this instrument, when fitted both to telegraph wires and to the protecting wire mentioned above, would probably permit of ascertaining the direction of induced and other currents, and would,

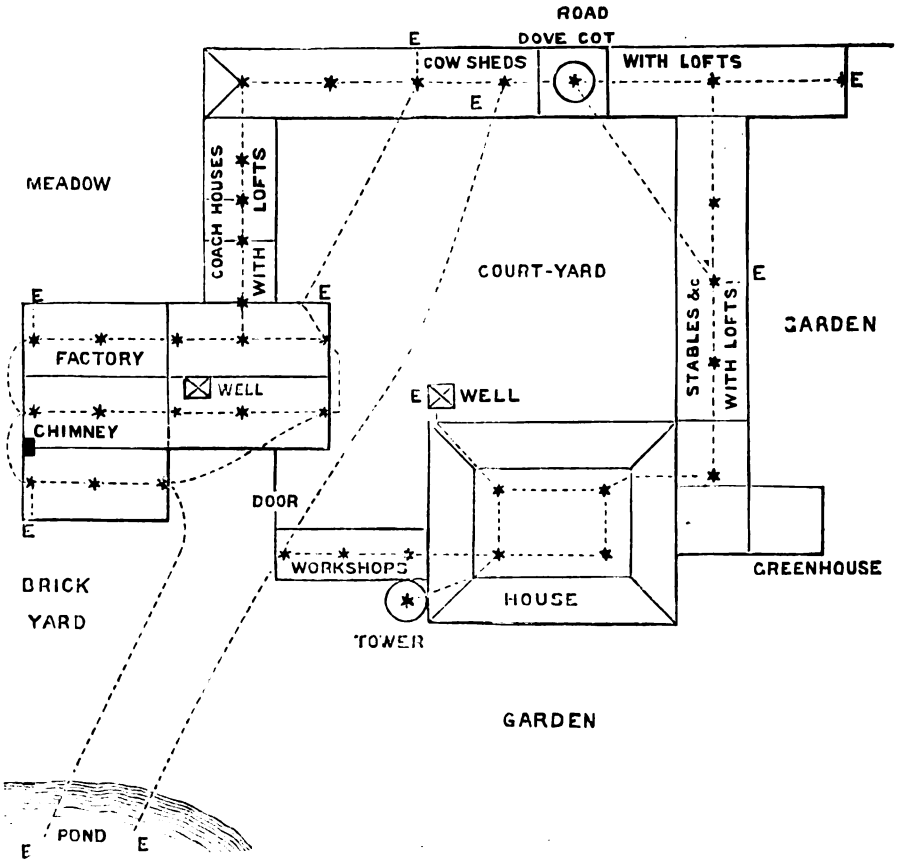

Fig. 5.—Farm Buildings.

Digitized by Google

also, when placed in suitable positions, probably afford valuable information as to the meteorological phenomena which accompany storms.

The application of this rhe-electrometer to lightning conductors generally would also permit of ascertaining the direction of the electric fluid, because there is reason, supported by Faraday's opinion, to believe that the lightning discharge commences from the earth more frequently than is generally supposed. If this be the case, a lightning conductor provided with numerous points is in a far better position for transmitting the electric fluid to the clouds than one having only a single point.

The lightning certainly took an upward direction in a remarkable discharge which occurred on 10th July, 1865, at the Antwerp Railway Station, and which cannot be accounted for by any of the theories at present admitted. The electric fluid passed through a pane of glass 4mm., = 0·15in., thick, in the station roof, making a hole like that produced by a projectile in an upward direction, moving at the rate of 100ft. to 150ft. a second, the edges of the hole being melted. Strange to say, the electric fluid passed through a bad conductor, while only a few centimetres distant were lead and iron conductors in perfect metallic connection with all the iron of the station, exceeding 120 tons in weight. But the anomaly does not stop here, because, to the right and left of the lantern in which was situate the pierced pane, the zinc roof of 2,500 square metres (26,910 square feet) weighs at least 15 tons, while three high lightning conductors were in immediate contact with the zinc, the whole being connected to twenty-eight cast-iron columns, which also serve to carry off the water from the roof.

The preventive as well as protective action of such a lightning conductor is shown by the observations, extending over several years, of Dr. Mann, President of the Meteorological Society, who states that, at Pietermaritzburg, in Natal, after the erection, at his instigation, of a large number of lightning conductors provided with numerous points, lightning shocks, which had been frequent, then became very rare.

M. Melsens is of opinion that insufficient attention is paid to the protection of small houses and farms in the country by means of inexpensive lightning conductors. Fig. 5 shows the plan of a farm protected under his direction, and, as he believes, placed in perfect security from lightning. The roofs, in nine different horizontal planes, are about 300 metres (985 feet) long. The *aigrettes*, to the number of 36, having altogether 210 points, are shown by stars; and the dotted lines represent the conductors, which follow the ridges or are suspended from one to another. There are 11 earth contacts, marked E, including two in the pond, and two others connected with the pump pipes of two wells. They are arranged so as to be always open to inspection; and testing with the galvanometer showed that there was scarcely any resistance to the current. The *aigrettes* are of the form shown at Fig. 6. They consist of iron wire of six or seven millimetres (about $\frac{1}{4}$ inch) in diameter, cut to lengths of 1, $\frac{3}{4}$, or $\frac{1}{2}$ metre, sharpened with a file, and tinned or galvanised. Five or six are bound together with wire and soldered, and then surrounded, by means of an iron mould, with a lump of zinc, leaving a groove for the conductor C. The *aigrette* is inserted in a hollow spike (Fig. 7), made out of gas pipe and galvanised, which is driven into the timber of the roof. The branches are then bent out so as to form an angle of 45° with the central point, as shown at Fig. 2. An exact account was kept of the cost of this lightning conductor; it is as follows:—

| | fr. | c. |
|---|---|---|
| 600 metres of iron wire, 6mm. = $\frac{1}{4}$in. in diameter | 91 | 30 |
| Total cost (labour and materials) of 37 *aigrettes*, with galvanised points, at 1fr. 60c. | 59 | 20 |
| Old zinc for joints of earth contacts, 20 kilogrammes at 0fr. 35c. | 7 | 00 |
| Solder, 2 kilogrammes at 2fr. 50c. | 5 | 00 |
| Labour, including fixing on roof | 150 | 00 |
| 120 hooks for fixing conductors | 24 | 00 |
| Pitch, tar, oakum, and drain-pipes | 20 | 00 |
| 10 cast-iron pipes, 420 kilogrammes at 8c. | 33 | 60 |
| £15 12s. 1d. = | 390 | 10 |

Taking an even sum, 400fr. or £16, this outlay represents 20c., or 2d., per square metre (1·196 square yard) of surface protected. The cost of lightning conductors on the Melsens system applied to three large public buildings in Brussels is, on an average, 66 centimes, or 6d. per square metre of surface protected. These are the Bourse (47c.), the new Palais de Justice (65c.), and the Hôpital St. Pierre (47c.). Compared with these figures, the protection on the old system of several large buildings cost on an average 4fr. 46c. (3s. 6d.) per square metre. Among them may be mentioned the king's palace at Brussels (3fr. 2c.), the king's stables (6fr. 23c.), the king's palace at Laeken (9fr. 68c.), and the hothouses at the Botanical Gardens (3fr. 99c.)

Sir William Thomson relates that when he urged the Scotch manufacturers to protect their works, they contended that it was cheaper to insure them than to erect lightning conductors. Now, M. Melsens wishes to change all that, and especially to eliminate the empirical element, so that "everywhere, both in town and country, one may afford the luxury of protecting one's habitation by a lightning conductor, just as one now has the luxury of a fireplace to counteract the cold, and a chimney to carry off the products of combustion." The *aigrettes* or brushes, such as are described above, may be made by a

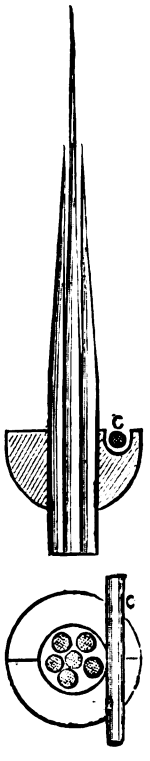

Fig. 6.—Aigrette.

Fig. 7.—Mode of Fixing Aigrette.

country blacksmith at a cost of 2s. to 2s. 6d. each, including both labour and materials, while a highly finished specimen in phosphor bronze may be produced for 12s.; at the same time it is far easier and cheaper to erect several small conductors than one large. M. Melsens has abstained from taking out any patents for his applications, but places his researches at the disposal of all. He also gives his advice freely to those constructors who consult him on the subject which he has so deeply studied. He contends that his lightning conductor, with its perfect and multiple earth contacts, but provided with numerous divergent points, placed on the exterior of an edifice, is represented by Faraday's cage, and that these points have certainly not the property of provoking electrical manifestations in the interior of a metallic frame-work in perfect communication with the common reservoir. The sharp points adopted are but a return to Franklin's original model, conical points more or less obtuse having been employed subsequently. There are many thousands of these points in Belgium—the Brussels Hotel de Ville is furnished with no less than 510; and yet, when properly tinned or galvanised they have not become blunt. Nor is there any record of a building thus protected having been struck by lightning. *Palmam qui meruit ferat.*

## THE ELECTRIC LIGHT ON BOARD SHIP.

Happily there is one sphere of usefulness in which the electric light can flourish without either the forcing heat of clever speculation or the chilling blast of foolish legislation. Nobody has yet projected a scheme for an ostensible monopoly of marine electric lighting, and not even the Board of Trade have yet contrived to bring it under the operations of the Electric Lighting Act. It speaks well for the electric light when left to itself, and ill for the Act which professes to regulate it, that in the one or two fields of operations which the Act cannot reach the light has prospered, whilst everywhere else it has languished or is at a standstill. Restricted by regulations which are impracticable and conditions which are prohibitive, the light which by this time might have made our streets brilliant and our homes charming has been virtually extinguished, mainly, as we believe, in obedience to political bigotry. The Board of Trade is at present controlled by such enlightened knowledge of the effects of monopoly, gained, if report speak truly, by close personal acquaintance with it on a large scale, that nobody outside the precincts of the Department is to be allowed to enjoy the temporary advantages which a monopoly confers. The existing monopolists have sinned past all redemption; in other words, they have served the public well, and have become rich; therefore there are to be no more monopolists, and nobody is to get rich if Parliament can prevent it, except individual traders who are able to put the screw on without help from Downing-street. The result apparently is, judging from the short experience we have had of this new departure in political economics, that the public is not served well—is not served at all, but is neglected, disappointed, and defrauded. The promoters of electric lighting have declined to act the philanthropist for the sole benefit of the public, and the public have parted with their money for benefits which they had a right to demand in return for privileges which they were very willing to concede.

Turning to fields outside the operations of the Act, we notice first of all that in theatres and public halls the light is making good progress. It was not to be expected that gas would be superseded everywhere and at once; it will suffice if new buildings adopt it in preference to gas, and this is certainly being done to a very encouraging extent, notwithstanding the extra cost of such independent installations in which the surrounding neighbourhood is not included. On board steamships the electric light does not suffer from these drawbacks, the illumination having in any case to be independent, and the competition being not against gas but oil. We wish we could furnish some exact statistics on this subject; but, after extensive inquiries, we are satisfied that the superseding of the old-fashioned mode of lighting on board steamships is proceeding very rapidly, and that, in fact, it constitutes the one lucrative form of business which the electric light companies are doing at present. In a very short time we may confidently look forward to the employment of electricity on board every ship propelled by steam power. The superiority of this mode of lighting, both as regards comfort, cleanliness, sweetness, and efficiency, is so manifest that it needs no advertisement. Steamships are now being fitted throughout with electric lamps, and in the engine rooms of some of the Atlantic passenger boats the lights are never out from the time of starting to the end of the voyage. If anything can add to the average discomfort of a sea voyage it is the make-believe light which a ship's lamp tries to give, and the smell it succeeds in giving. Its supersession by the electric lamp is a transformation which every sea voyager will rejoice at, and will very soon consider indispensable. So far there has been no accident that we have heard of in connection with this mode of lighting in the ordinary way. The recent fire on board the "Rebecca Everingham," if correctly ascribed to the falling of burning carbon, must have been the result of gross carelessness in using arc lights inadequately protected, which, if this is the American method of lighting, has happily not been imitated by the English shipping companies.

Some interesting experiments are just now being made on board two different classes of steamships by the firm of Siemens Brothers. The Peninsular and Oriental passenger boat "Massalia" now in the Royal Albert Docks is fitted with Swan lamps throughout on a single wire system, or what may be called the earth system, and promises to be a complete success. The "Riachuelo" is an ironclad lying in the Victoria Docks, recently built for the Brazilian Government, and is the first man-of-war that has been so fitted. She is lighted throughout by Swan lamps, 270 of which are fixed in all parts of the ship.

Digitized by Google

In this case the double or return wire system is adopted; and each lamp has a special appliance intended to guard it against the concussion consequent upon the firing of the guns. On deck there is a Siemens search light, and the whole are maintained by two Siemens machines (a third being kept in reserve), driven by a Brotherhood three-cylinder engine. Last Friday a number of visitors inspected these two ships, which are fine specimens of the classes they respectively represent; and as illustrative of the uses to which the electric light may be put for the purposes of peace and of war the exhibition was a most encouraging one. Until better times set in for the electric lighting business on land, we should advise its being pushed energetically on the high seas.

## CORRESPONDENCE.

### CHARACTERISTIC CURVES OF DYNAMO-ELECTRIC MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: May I ask through your columns for some information as to the proper mode of tracing and reading these curves? It is a subject of very deep interest to all who have daily to do with dynamos. I am not aware of a single English book treating of the subject, and I am confident that an exhaustive article on this point would be welcomed by many besides myself.

I also want to know whether varying the E.M.F. of a current passing through the coils of an electro-magnet, whilst keeping the current constant, has any effect on the magnetism of the magnet?—Yours, &c., NYWLA.

Benares, March 18, 1884.

### ON THE EFFICIENCY OF DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Dunston's letter on the above subject he refers to certain trials of Bürgin dynamos recorded in *The Electrician*, September 23, 1882, and asks for information, which I will gladly give him.

The trials were made in June, 1882, and refer to one machine tried under various conditions.

Those in Table I. were made with a $C_3$ armature in the machine, the four arms of the field magnets being coupled, two parallel and two in series, as a shunt to the external circuit. This arrangement gave the largest electrical output, but at the cost of considerable waste of power in the magnets; hence the efficiency was low.

Those in Table II. were made with the same armature, but the four arms of the magnets were coupled in series again as a shunt to the external circuits. The strength of the magnetic field being reduced, the output was less but the efficiency higher.

Those in Table III. were made with an armature having fewer turns on it, put into the same field magnets, coupled all four arms in series, as in Table II. This combination gave the most favourable results. As I have not our test book available for reference I must describe the trials from memory. They were carried out as follows:—

The dynamo was driven by a steam engine. The horse-power was measured by indicator diagrams, three or four of which were taken at each trial.

"*The horse-power transmitted to the dynamo*" was obtained by deducting from the gross indicated power the power absorbed by the engine friction only. To enable this to be done correctly, frictional diagrams were taken at frequent intervals, and the engine friction calculated therefrom.

What we have called "horse-power transmitted to dynamo" is identical with what your correspondent and others have called "horse-power delivered to pulley," "horse-power in belt," "actual horse-power absorbed," &c.

The electrical measurements were carefully taken; the resistances of the various parts of the circuit were taken cold, and afterwards when heated by working. The resistances entered at the head of the tables were measured when cold. The total resistances upon which the currents depend were measured when heated, and consequently do not check exactly with the others.

The currents in external circuits and in field magnets, and the E.M.F. at brushes, were measured by Siemens' dynamometers, and Ayrton and Perry's voltmeters, both freshly calibrated. The currents and E.M.F. in armature were calculated.

Mr. Dunston will find that the total resistance of the circuits in Trial 1, Table I., does check within a trifling fraction with the parts thereof, although it was not calculated, but measured independently.

| | | Ohms. |
|---|---|---|
| Thus, | R. of magnets ..... | 10·5 |
| | R. of armature ..... | 0·545 |
| | R. of ext. circuit..... | 3·310 |

Then $$\frac{10{\cdot}5 \times 3{\cdot}310}{10{\cdot}5 + 3{\cdot}310} = 2{\cdot}516.$$

To which add R of armature = 3·061 instead of 3·055, a difference of ·006 ohm only.

Your correspondent can obtain the "total mechanical efficiency" he asks for by dividing the "total electrical horse-power by the horse-power transmitted to dynamo, both being given in our tables. In Trial 1, Table I., this is 96 per cent., but no doubt requires correction on account of the recent alteration in value of the ohm.

To obtain the "total electrical efficiency" we should have had to run the dynamo with brushes off, as he suggests.

But I may remind him that, after all, these two efficiencies are of little practical importance, except to those interested in tracing out the want of efficiency in a faulty dynamo.

At the time we carried out these trials we were content with showing a high efficiency in

$$\frac{\text{Electrical output}}{\text{Horse-power transmitted.}}$$

Nowadays we ought to go a step further, and show a high efficiency in

$$\frac{\text{Electrical output}}{\text{Gross indicated H.P. of engine.}}$$

Many modern high-speed dynamos, which require counter-shafting and belting to be interposed between the engine and dynamos to get up sufficient speed in the latter, will show very low efficiency when measured by this standard.

I quite agree with your correspondent that it is highly desirable that manufacturers of dynamos should fix upon a uniform method of carrying out trials, so that machines of various types could be fairly compared. But to do this there must be uniformity in the mode of testing the power transmitted to the dynamo, as well as in tabulating the results.

In our own case we have adhered to the plan of measuring by taking indicator diagrams, because after all it is the measure of our customers' coal bills. Moreover, it is a well recognised and accurate mode of measuring power. But we should be the first to welcome a transmission dynamometer, if one could be produced sufficiently trustworthy in its readings and handy in use.

As surmised by Mr. Dunston we intend to publish tables showing results greatly in advance of those above referred to. I have recently tried a machine (the one referred to by Mr. Preece in his recent paper at the Society of Arts) with the following results:—

With outputs varying from 5½ to 19½ electrical horse-power the average

$$\frac{\text{Electrical output}}{\text{Horse-power transmitted}} = 92 \text{ per cent.,}$$

and the

$$\frac{\text{Electrical output}}{\text{Gross ind. H.P. of engine}} = 71 \text{ per cent.,}$$

and this last in our case reached 82 per cent.

Digitized by Google

Although the armature of this new machine was no larger than that of the $C_3$ Bürgin referred to in the old trials, the useful electrical output was increased from 5·3 horse-power to 19·5 horse-power, and the commercial efficiency from 64 per cent. to 92 per cent.

This increase of output and efficiency was obtained with a decrease in speed from 1,800 revolutions to 1,000 revolutions per minute.

Calculated roughly, about (·026lb.) of copper is used per watt of useful output. At the maximum output of 14,000 watts or volt-amperes there is no sign of sparking at the brushes, and the machine keeps cool through a ten hours' run.

—Yours, &c., R. E. CROMPTON.

Mansion House-buildings, March 24.

## THE AXIAL MOTION OF THE EARTH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with considerable interest the article on the above subject which appeared in *The Electrician* of 22nd March, as quoted from the *Scientific American*, the remarks in which throw doubt on the accuracy of the Foucault pendulum. It struck me that the conclusions arrived at by the experimentalists were scarcely the results of careful investigation, but were too hasty. The scientific gentleman of Dundee mentioned in the *Liverpool Journal* was evidently vexed with his experiments when he concluded that he had proved the Foucault pendulum to be a "gross delusion;" and regarding the Rev. H. H. Jones, F.R.A.S., referred to in the *Manchester Examiner*, who found "the rate of variation (?) entirely different to the accepted theory," I think if he were to make another trial he would find some cause for what took place not quite inconsistent with the theory of the Foucault pendulum.

It is a great pity, however, that the scientific gentlemen who have tried these experiments and failed did not register some details of the pendulum under trial as to the way in which it was mounted, its dimensions, the surrounding space, time, &c., because with such data those who have succeeded with their trials of the Foucault pendulum might be able to point out the cause of the failures alluded to.

The greatest care is necessary in conducting such experiments. The point from which the pendulum is to be suspended should be rigid, and out of reach of any disturbing force, such as the jarring of the building, or currents of air.

When the Foucault pendulum was tried in 1851 at the Polytechnic Institution, London, there were many persons who disbelieved in its action. Some thought it absurd to suppose that a disc or table placed under the pendulum would turn on an axis of its own, and that the pendulum should be placed at the poles to show the rotation. Others declared it to be inaccurate in its motion, because the disc turned in 30 hours, the earth's rotation on its axis taking place in 24 hours. This circumstance was, however, one of the best proofs of its accuracy, inasmuch as it indicated the latitude of London.

There are some persons who may not be aware that when a wheel or disc rotates every spot on its surface rotates on an axis of its own, and this may be practically illustrated by the turning of the crank of a steam engine in the brasses of the connecting rod; the crank axle in rotating imparts an induced rotatory motion to the crank as well as carrying it round its own centre. The Foucault pendulum depends upon this induced rotatory motion of any spot on the surface of the earth to illustrate the fact that the mass of the earth rotates on its axis.

It is only necessary, therefore, to know that the earth does revolve on its axis to be assured that, if the Foucault pendulum is applied with proper care and delicacy of adjustment, it ought to indicate the rotation by the change of the relative positions of the pendulum-bob and the points marked on the table beneath it.

Of course it is very difficult to convince those persons who do not believe in the axial motion of the earth, because such people seldom trouble themselves with investigations of any kind, and therefore they remain ignorant of the many scientific proofs of the earth's diurnal rotation, which, according to astronomers, takes place in 23 hours 56 minutes 4·09 seconds, carrying the equatorial surface of the globe round at the rate of about 1,000 miles an hour from west to east.

I have myself tested the Foucault pendulum, and my experiments have proved successful, in consequence of which I devised a means of sustaining its vibrations, and have constructed an electric apparatus which will effect this object without the least bias to the direction the pendulum should take.

With reference to the induced rotations of the particles of a revolving mass, we may assume a spherical shape for each, possessing an infinite number of axes. Such a particle, therefore, in a revolving body performs at the same time, though at different rates of velocity, revolutions on axes at every angle between the common axis of the mass and that axis of its own at right angles to it on which it has no angular motion. If such a particle could be separated from a rotating mass without stopping or altering its rotation it would exhibit a very peculiar rolling motion, something in appearance like the convolutions of those wonderful little microscopic creatures called "rotifers."

On the surface of the globe every spot situated between the poles and the equator turns on its axis at right angles to the surface at a velocity varying with its position.

This may be illustrated by a disc of cardboard, with an axis fixed at right angles to it. If a spot be marked on the surface of the disc, and it is turned once on its axis, the spot will have also turned once besides, having been carried round the common axis. If the card disc be divided into sectors, and one or more be cut out, and the edges of the remaining portion joined, the disc will become a cone; but it will be found that for one revolution of the cone on its axis the spot will only make a portion of a revolution. The rotation of these spots can be easily made apparent on a small scale by means of very simple apparatus.

The latitude of London is 51° 30′ 49″, and the sine of that angle is ·78275. Then, $360° (1 - ·78275) = 78° 12′ 36″$, which would be the sector to be cut from a disc to make a cone whose surface would represent the zone of the latitude of London; and if such a cone were turned once on its axis in 23h. 56min. 4·09sec., then the time required for the spot representing London to make a complete turn would be

$$\frac{\text{h. m. sec.}}{\sin. 51° 30′ 49″} \quad \frac{24\ 56\ 4·09}{·78275} = 23·93447 = 30·6 \text{ hours};$$

and this was the time of a revolution of the disc under the Foucault pendulum when shown at the Polytechnic in 1851.

I am afraid I have been explaining what was already known to most of your readers, but my apology must be that I am offering my explanations to gentlemen who condemn that very wonderful instrument, the Foucault pendulum, as a "gross delusion."—Yours, &c., B. P. STOCKMAN, M. Inst. C.E.

## ON THE HEATING EFFECTS OF ELECTRIC CURRENTS.*

BY WILLIAM HENRY PREECE, F.R.S.

The production of heat in electrical conductors due to the transference of electricity through them has become a matter of very great practical importance. A knowledge of the variation of the law, due to the dimensions and character of the conductor, is essential for lightning protectors and for the leads of electric lights.

Atmospheric electricity has proved a great danger to insulated wires, subterranean and submarine, and to telegraphic apparatus generally. Not only do the direct discharges of atmospheric electricity enter the wires, but very powerful currents are induced in neighbouring wires when these discharges take place, either between cloud and cloud or between cloud and earth. Various plans have been devised to protect apparatus and wires from these currents. Lightning protectors

based on the effect of points, on the facility of discharge through vacua, on the low resistance of thin air-spaces to high potential, and on the fusibility of thin wires, have been used.

The most careful and long-continued observations have shown that the survival of the fittest is found in the use of a thin flat air-space, A (Fig. 1), supplemented by a fine, well-insulated protecting wire, B, of high resistance wound around a brass rod in connection with earth. The air-space is obtained by superposing two smooth plane surfaces of thick brass, separated from each other by a space of ·004 of an inch, by means of a frame of mica or paraffined paper. It requires (according to the researches of Messrs. Warren De La Rue and Hugo Müller,* confirmed by my own observations made in Warren De La Rue's laboratory), a potential of 800 volts to strike across such an air-space, and when this is done a path of no resistance, according to Faraday, is established for the atmospheric discharge to flow to earth. But destructive currents of induction are often produced in telegraph wires, which have not the requisite potential to strike across this air-space, and the element of *time* may enter to force some of the current into the cable or apparatus so as to injure it. Hence a protecting wire has been added, which, while it will allow all working currents to pass without retardation, will not allow a current strong enough to damage the cable to flow through without its being fused. It thus acts as a safety valve. The length and dimensions of this wire have not been hitherto determined by any stringent conditions. After having determined the conditions required to give the maximum effect with the so-called "plate protector"† I became anxious to find out the conditions that would give a similar result with the "wire protector."

Now, the very strongest current that can, under any possible circumstances, enter a wire from the working batteries is one of 500 milliamperes (·5 B.A. unit current), while atmo-

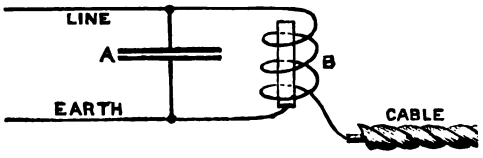

Fig. 1.

spheric currents enter the wires of all strengths from 1 milliampere to 30 or 40 amperes, or even more. Therefore, it was desirable to find that wire which would not fuse with 500 milliamperes, but would fuse with currents of about 700 milliamperes and over.

Hence, I took a source of electricity, which was a large thermopile of Clamond's make, which would give the necessary current, a rheostat by which it was possible to regulate this current to any strength, a Thomson mirror galvanometer, which enabled me to measure, record, and regulate every change of current, and a discharger, by which I was able to hold, measure, and adjust the wires to be tested.

1. With a given current and a uniform wire of given diameter and given material the effect, allowing for the cooling effect of the binding screws, was independent of the length, for whether the length experimented upon was an inch, a foot, or a yard, it always fused when the current reached a certain definite strength. The point of fusion was irregular, for it simply depended on some irregularity in the uniformity of the wire, and the weakest link in the chain went.

2. Samples of platinum wire of various diameters, each of 6in. in length, were taken, and the current increased gradually until the wire fused. The results are given in the following table :—

| Diameter in inches. | Fusing current in amperes. |
|---|---|
| ·00050 ..... | ·277 |
| ·00075 ..... | ·356 |
| ·001 ..... | ·437 |
| ·002 ..... | ·790 |
| ·003 ..... | 1·150 |

* *Phil. Trans.*, Part II., Vol. 174. † British Association, 1880.

These figures are the average of numerous experiments, and they are plotted out in Fig. 2.

The general law governing the ratio between the current strength and the diameter of the wire when the latter is raised to a definite temperature, and where radiation is free and unchecked by any athermanous envelope, appears to be that the current should vary as the diameter × $\sqrt{\text{diameter}}$.* This may be proved as follows :—

The heat developed in any cylindrical wire is, by Joule's law,

$$H = C^2Rt, \text{ where } R = \frac{\cdot 2\rho l}{\pi d^2},$$

$\rho$ being the specific resistance, $l$ the length, and $d$ the diameter of the wire, then

$$H = C^2 . \frac{2\rho l}{\pi d^2} . t = \mu \left(\frac{C}{d}\right)^2;$$

or if we maintain the ratio between the current and the diameter constant, the same amount of energy will be wasted in the conductor.

But the temperature of the conductor is dependent on the rate at which the heat is radiated and conducted away, and when the heat imparted by the current just balances that lost by radiation and convection the temperature becomes constant. But the heat lost varies with the surface, and the smaller the surface the less the loss, and therefore the temperature will vary with the diameter. Hence as

$$H \propto \mu \left(\frac{C}{d}\right)^2, \text{ and also } H \propto d,$$

therefore

$$\frac{C^2}{d^2} = d; \text{ or } C = d\sqrt{d}.$$

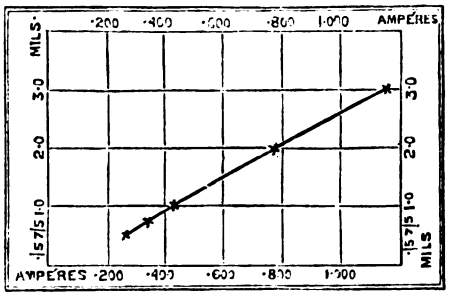

Fig. 2.

The results of the foregoing experiments on the current required to fuse wires of different diameters would appear to contradict this law, and to show that the current varies as the diameter, but there are several elements in the method of making the measurements which tend to modify the general law. Platinum wires—especially those of small diameter—are liable to flaws which practically reduce their effective diameter to a great extent; also the larger wires, from their greater weight, necessarily tend to part asunder at a lower temperature than those which are lighter and on which the strain is less.

3. In thermometric measurements there are only two fiducial points usually employed, viz., the freezing point and the boiling point, but there are two other points equally well marked, though perhaps not quite so accurately fixed. These are the points of self-luminosity and of fusion. The first point has been determined by Daniel to be $\left\{\begin{matrix}980^\circ \text{ F.} \\ 526^\circ 6 \text{ C.}\end{matrix}\right\}$ and by Draper at $\left\{\begin{matrix}977^\circ \text{ F.} \\ 525^\circ \text{ C.}\end{matrix}\right\}$, and it has been shown by the latter observer that this is true for all substances.

I was anxious to discover whether the law before stated would apply in the case of the production of the lowest visible red radiations by currents. I therefore took several wires of different materials, and of different diameters, but all of the same length, and by observing them in a carefully constructed dark chamber, determined the currents that produced self-luminosity, these currents being measured by finding the difference of potential at the ends of a thick German silver wire

D Current calculated from the formulæ ·057465 × $d\sqrt{d}$.

The results are plotted out in Fig. 3. It will be seen that the observed and calculated results agree to a considerable degree of accuracy, except in the case of platinum, which behaves as in the previous experiments, and is generally found to be irregular in its quality.

These experiments were made upon wires exposed to the air, where radiation is free. I am anxious to repeat them upon wires covered in insulating material and buried in the ground, but I have not been able to do so up to the present moment. The law with reference to such wires has a very important bearing on the size of electric light leads, for it shows the necessity of making them large enough to prevent the possi-

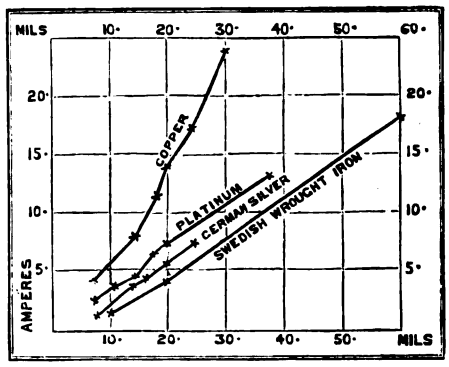

FIG. 3.

bility of their being heated above normal temperatures, otherwise points of danger are very easily reached by increments of current.

## CLAUSIUS ON THE THEORY OF THE TRANSMISSION OF POWER BY DYNAMO-ELECTRIC MACHINES.

(CONTINUED FROM PAGE 489.)

Equation (25) shows that the value of $r_2$, which corresponds to the maximum value for $T_2$, is not equal to $\frac{1}{2} r_1$, as the rule mentioned above would have it, but that it approaches this value as the value of $r_1$ itself increases.

5. *Determination of the Work $T_2$ when the Work $T_1$ is Given.*

The second assumption which may be made as to the source of power used for driving the first machine is that it can only deliver a definite quantity, $T_1$, of work ; we have then to inquire how, under these circumstances, the work to be obtained from the second machine, or $T_2$, depends upon the mode in which the machines are worked. Here we must first remark that if $T_1$ is given, only one of the two velocities of rotation, $r_1$ and $r_2$, is to be considered as independent ; for between the five quantities $r_1$, $r_2$, $T_1$, $T_2$, and $i$, there are three equations, III., V., and (3) ; and hence if two of these magnitudes are given we can determine the other three. We will select $r_1$ as the magnitude which, with $T_1$, is to serve for determining the three other magnitudes $i$, $r_1$, $T_2$. In order to express $i$ as a function of $T_1$ and $r_1$ we may use equation III., viz. :—

$$T_1 = \left[\frac{e+i}{(a+i)(b+i)} p r_1 + \left(\frac{l}{a+i}\right)^2 \left(\sigma + \frac{\lambda}{b+i}\right) r_1^2\right] i^2.$$

This may be written in the following form :—

$$\frac{(e+i)\,i^2}{(a+i)(b+i)} = \frac{T_1}{p r_1} - \left(\frac{l\,i}{a+i}\right)^2 \left(\sigma + \frac{\lambda}{b+i}\right) \frac{r_1}{p} \quad . \quad (26).$$

The solution of this equation, according to $i$, is complicated by the term on the right-hand side, which contains $i$ in the denominator at a higher power than the term on the left-hand side. But we must remember that each term on the right-hand side contains the factors $\sigma$ or $\lambda$, which are so small that we may neglect quantities which contain them in any degree above the first. We may make use of this fact by first determining that value of $i$ which the equation gives if we neglect all the terms containing the factors $\sigma$ and $\lambda$. If, for

Digitized by Google

distinction, we call this value $i'$, the equation determining it is as follows:—

$$\frac{(e+i')\,i'^2}{(a+i')\,(b+i')} = \frac{T_1}{p\,r_1} \quad . \quad . \quad . \quad . \quad . \quad . \quad (27).$$

The value $i'$ thus obtained differs from $i$ only by a magnitude of the same order as the factors $\sigma$ and $\lambda$. If we now go back to the equation (26), and in the terms which contain these factors replace $i$ by $i'$, the expression on the right-hand side is only changed by a quantity which is of the second order as compared with $\sigma$ and $\lambda$, and may therefore be neglected. In this way we form instead of equation (26) the following:—

$$\frac{(e+i)i^2}{(a+i)\,(b+i)} = \frac{T_1}{p\,r_1} - \left(\frac{e\,i'}{a+i'}\right)^2\left(\sigma + \frac{\lambda}{b+i'}\right)\frac{r_1}{p} \quad . \quad (28).$$

Here for simplicity we will introduce the following symbol:

$$z = \frac{T_1}{p\,v} - \left(\frac{l\,i'}{a+i'}\right)^2\left(\sigma + \frac{\lambda}{b+i'}\right)\frac{r_1}{p} \quad . \quad . \quad . \quad (29).$$

The equation then becomes

$$\frac{(e+i)i^2}{(a+i)\,(b+i)} = z \quad . \quad . \quad . \quad . \quad . \quad . \quad (30).$$

The two equations (27) and (30) are of similar form, so that the solution of one gives at once that of the other. If we select equation (30) we may bring it into the form of an ordinary cubic equation by multiplying by $(a+i)\,(p+i)$.

This equation is

$$i^3 - (z-e)\,i^2 - (a+b)\,z\,i - a\,b\,z = 0. \quad . \quad . \quad (31).$$

We may apply to this the ordinary methods of solution for cubic equations. Of the three roots only one, on account of its sign, is applicable in the present case, and this may be determined as follows:—Let $\phi$ be the angle lying between 0 and $\pi$, which satisfies the equation

$$\cos\phi = \frac{(z-e)^3 + \frac{9}{2}(a+b)\,(z-e)\,z + \frac{27}{2}a\,b\,z}{\sqrt{[(z-e)^2 + z\,(a+b)\,z]^3}} \quad . \quad . \quad (32).$$

Then $i$ will be determined by the following expression:—

$$i = \frac{1}{3}(z-e) + \frac{2}{3}\sqrt{(z-e)^2 + z\,(a+b)\,z} \times \cos\frac{\phi}{3} \quad . \quad . \quad . \quad (33).$$

As regards the cosine which appears as a factor to the last term, it will be seen from equation (32) that as $z$ increases from 0 to infinity, the angle $\phi$ decreases from $\pi$ to 0. Hence $\phi/3$ decreases from $\pi/3$ to 0, and accordingly cos $(\phi/3)$ increases from $\frac{1}{2}$ to 1. We may remark that the increase is at first extremely rapid, so that for values of $z$ which occur ordinarily in practice cos $(\phi/3)$ is not very different from 1.

We may now apply equations (32) and (33) in two ways. If we replace $z$ by the expression $T_1/p\,r_1'$, the equations give us the solution of equation (27), and determine that approximate value of $i$ which we have above distinguished as $i'$. Substituting this value in equation (29), we determine the magnitude $z$; and this being known, a second application of equations (32) and (33) will give us a more exact value of $i$.

When we have in this way determined the intensity of current $i$, which is the first of the three magnitudes mentioned above, the other two offer no difficulty.

To determine $r_2$ we may use equation (5). This is an equation of the second degree, and may be solved as such; but here again the circumstance that the terms containing $r_2^2$ contain also the small factors $\sigma$ and $\lambda$ may be used to facilitate the calculation, for we may write the equation in the following form:—

$$r_2 = \frac{\frac{e+i}{(a+i)\,(b+i)}\,p\,r_1 - R - \rho\,r_1 - \left(\sigma + \frac{\lambda}{b+i}\right)\left(r_1^2 + r_2^2\right)}{\frac{e+i}{(a+i)\,(b+i)}\,p + \rho} \quad . \quad (34).$$

Here we may at first neglect the last term of the numerator, and then deduce an approximate value for $r_2$. We may then introduce this value in the last term, and by a second calculation find a more exact value for $r_2$.

When we have thus determined $r_2$, the determination of the last and most important of these magnitudes, viz., the work $T_2$ which is done by the second machine, is perfectly easy. It is given by equation (20), which, if we replace $\gamma$ and $\delta$ by their values, may be written as follows:—

$$T_2 = T_1 - \left[R + \rho\,(r_1 + r_2) + \left(1 + \frac{l^2}{(a+i)^2}\right)\left(\sigma + \frac{\lambda}{b+i}\right)(r_1^2 + r_2^2)\right] i^2 \quad (35).$$

We see by this equation, in which the negative term on the right-hand side has the factor $i^2$, that $T_2$ is greater (or approaches more closely to the given value of $T_1$) the smaller is the value of $i$. But by equation (33) $i$ diminishes as $z$ diminishes, and again the expression for $z$ given in equation (29) has as its chief term $T_1/p\,r_1$, and therefore diminishes as $r_1$ increases. Hence it follows that $i$ diminishes as $r_1$ increases, and we thus arrive at the result for $T_2$ that its value is greater as the value given to $r_1$ is greater. In fact, practice has also shown that in order to make $T_2$ as large as possible in comparison with $T_1$, the velocity of rotation of the first machine must be raised to the highest practicable limit.

Again, the velocity $r_2$ of the second machine, by equation (34), will be greater as $r_1$ is greater and as $i$ is less. But from what has gone before it appears that for a given value of $T_1$ any increase in $r_1$ produces a diminution in $i$. Hence equation (34) shows that as $r_1$ increases, $r_2$ increases at a yet more rapid rate.

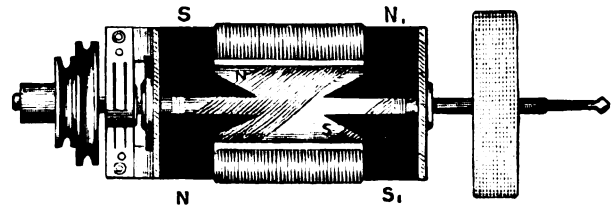
In the case in which T is taken as fixed there can be no question of any definite relation between $r_2$ and $r_1$, for which $T_2$ is a maximum, as is easily seen from what has gone before.

Just as in this section the three magnitudes $i$, $r_2$, and $T_2$ have been determined from the given magnitudes $T_1$ and $r$, and as in previous sections the magnitudes $i$ and $T_2$ have been determined from $r_1$ and $r_2$, so may a series of different calculations be made from the same equations, inasmuch as we may choose any two of the five magnitudes $i$, $r_1$, $r_2$, $T_1$, $T_2$, and from them determine the three others. We shall here, however, content ourselves with the two examples already given, which refer to the two most important cases in practice. With regard to the results of these calculations, which may perhaps appear to have in some degree a less simple form than is desirable for practice, it may be remarked that the object was to deduce the results from the main equations on the principle of neglecting only the higher powers of the small quantities $\sigma$ and $\lambda$. Those who are satisfied with a less degree of accuracy can easily simplify the calculations and the data which they give. Moreover, when once the results flowing from the main equations are known, it will not be difficult to construct approximate formulæ, which will represent these results with sufficient accuracy for practical purposes, and will be more convenient for ordinary use. Such transformations would, however, be beyond the scope of the present paper.

Bonn, January, 1884.

## IRISH'S NEW ELECTRO-MOTOR.

This motor has been devised in consequence of the demand for small and most effective portable motors. The illustration



represents a convenient form for domestic and other uses, where small power only is required, and is fitted with universal tool-holder for brushes, emery wheels, drills, &c.; also sheaves and friction wheel. Although a hand machine, it may be easily clamped to the bench or table. The field magnets are simply electro-magnets, with pole pieces projecting inwards, and hollowed to receive the armature, which is of Siemens form, with a twist which brings one pole opposite N N, the other opposite S S. The machine also acts as a dynamo.

## ELECTRIC CONDUCTORS.

BY MR. W. GEIPEL.

Although it is impossible to lay down any hard-and-fast rules for the proper size of conductors for electric lighting, owing to the variety of questions arising, yet the table which we publish herewith will, it is hoped, afford valuable assistance to electrical engineers in making installations, with a view to economy of metal, together with an even distribution of the light.

It will be remembered that Sir W. Thomson, at the British Association meeting at York, in 1881, discussed the question of "Economy of Metal in Conductors of Electricity" (*vide The Electrician*, Vol. VII., p. 295). The following explanations will give the method pursued in constructing the table :—

If C = current in amperes.
R = resistance of conductor in ohms.
$a$ = sectional area in inches.
$l$ = length in yards.
H = total annual cost in £'s per electrical horse-power, *i.e.* the cost per hour multiplied by the number of working hours per annum.
W = weight of conductor in tons.
S = cost of conductor in £'s per ton, including an allowance for insulation and laying down, &c.
$p$ = interest and depreciation per cent. on first cost of conductor.

Then horse-power lost in heat $= C^2 \times R \times \cdot00134$.

Allowing for copper of 95 per cent. conductivity,

$$R = \frac{\cdot000024356\, l}{a}.$$

Loss in £'s per annum by heating

$$= C^2 \times \frac{\cdot000024356 \times l}{a} \times \cdot00134 \times H. \quad . \quad . \quad (1)$$

Cost of conductor $= W \times S$.

Loss in £'s per annum in interest and depreciation

$$= W \times S \times \frac{p}{100}.$$

Taking specific gravity of copper = 8·95,

$$W = 3\, l \times \frac{a}{144} \times \frac{8\cdot95 \times 62\cdot425}{2240}.$$

Loss in £'s per annum by interest and depreciation

$$= 3\, l \times \frac{a}{144} \times \frac{8\cdot95 \times 62\cdot425}{2240} \times S \times \frac{p}{100} \quad . \quad . \quad . \quad (2)$$

From (1) and (2) the total annual loss

$$= C^2 \times \frac{\cdot000024356}{a} \times l \times \cdot00134 \times H + 3\, l \times \frac{a}{144} \times \frac{8\cdot95 \times 62\cdot425}{2240} \times S \times \frac{p}{100}.$$

The amount of $a$ to make this a minimum (which is also that which makes the two constituents (1) and (2) equal) is as follows :—

$$a = \sqrt{\frac{C^2 \times \cdot000024356 \times l \times \cdot00134\, H \times 144 \times 2240 \times 100}{3 \times l \times 89\cdot5 \times 62\cdot425 \times S \times p}}$$

$$= C \times \cdot025618 \sqrt{\frac{H}{S \times p}}.$$

It will be seen that the sectional area of copper is independent of the length of the conductor, but proportional to the current.

In the table the areas are, for convenience, given for a current of 100 amperes. Interest and depreciation are taken at 15 per cent. per annum ; for other values multiply the area given in the table by $\frac{3\cdot873}{\sqrt{p_1}}$, $p_1$ being the desired percentage, interest, and depreciation.

The cost and fall of potential for 100 yards are given, from which the weight and resistance can be easily deduced.

$$\text{Resistance of 100 yards} = \frac{\text{Fall of Potential}}{\text{Current}}.$$

$$\text{The weight of copper in tons per 100 yards} = \frac{\text{Actual Cost}}{\text{Cost per ton}}.$$

The columns giving the fall of potential are intended to assist in the even distribution of the light ; *e.g.*, supposing we have a lamp 100 yards away from the rest of the lamps, in order to maintain the same candle-power it will of course be necessary to lay down a heavier conductor. The lamp requires one ampere at 50 volts, and we can afford to lose, say, two volts. Then the potential fall per 100 yards should be one volt, and in the table we find the requisite area to be ·0024 square inch ; and conversely, if the lamp be nearer the generator than the rest, and the difference of potential between the mains at the branch connection is, say, 55 volts, and the lamp is twelve yards from the mains, the branch conductor then must have a resistance of 5 ohms. In the table we find the resistance of No. 30 I.S.W.G. (copper) to be 20 ohms per 100 yards, *i.e.*, 5 ohms per 25 yards, which will satisfy the conditions. The columns giving the cost of the conductor per 100 yards may be useful in working out an approximate estimate quickly.

For large conductors the economical area is in some cases exceeded by the safe working area ; it would therefore appear advisable in such cases to employ a number of conductors rather than a single conductor, otherwise one having a rectangular or some other section affording a larger cooling surface than a circular section. There is also given at the bottom of the table the safe working amount of area per 100 amperes for circular conductors of various sizes, so calculated that the ratio between the cooling surface of the copper and the heat generated therein is maintained practically constant, allowing for rise in temperature of between 15° and 20° Centigrade.

The formula used was safe current $= 750\, d^{\frac{3}{2}}$ ; $d$ = diam. in ins. From this formula is also worked the safe current for different numbers of the Imperial Standard Wire Gauge.*

---

## RECENT PROGRESS IN DYNAMO-ELECTRIC MACHINES.†

By Professor SILVANUS P. THOMPSON, B.A., D.Sc., M.S.T.E.
University College, Bristol.

(CONTINUED FROM PAGE 491.)

Passing from ring armatures, I come to another type of machine having disc armatures. The earliest machine of this type was due to the indefatigable Mr. Edison, who built up his disc of radial bars connected at the outer ends by concentric hoops, and at the inner by plates or washers. Each radial bar communicates with the one opposite to it ; and the disc thus built up is rotated between the cheeks or pole-pieces of very powerful field-magnets, which very nearly meet, and which therefore yield an enormously powerful field. I cannot hear of any of these disc dynamos having yet come into practical use.

Another type of disc-dynamo has been invented by Sir W. Thomson. In this case the armature is a flat wheel, very like a flattened bicycle wheel. It is shown at $a$ in Figs. 26, 27, and 28.‡ The radial arms or spokes of the wheel, in which

* At a meeting of the Society of Telegraph Engineers and Electricians, on December 13th, 1883, Mr. Blakesley pointed out that it was necessary to include in Sir W. Thomson's formula terms involving cost of insulation and installation, &c. However, the introduction of such terms would tend to complicate a table which is intended rather for all practical electricians than for the, unfortunately, comparative few who are skilled mathematicians ; so that, perhaps, the method which had already been adopted in compiling the table, viz., of including in the cost of the conductor the cost of insulation and installation, may prove to be the rea lier.

† Paper read before the Society of Arts, Feb. 23, 1884.

‡ Figs. 26, 27, and 28 refer to diagrams given in the patent specification of Sir W. Thomson's wheel dynamo.

Digitized by Google

the currents are induced, are all connected at their external ends to the copper rim, but at their internal ends are carefully insulated and connected each to a segment of a collector or commutator, *g*. As in Edison's disc machine, so also in this, the thin disc rotates between the poles of very powerful field-magnets, which, in the case of Sir W. Thomson's machine, are semi-circular in form. Sir W. Thomson also pivots his armature with his axis vertical, and spins it like one of his gyrostats. Unfortunately, the machine has not shown itself to be in practice a success. Its construction necessitates a very high speed, else the electromotive force would be small. If the radial bars, instead of being all joined to one rim, were united

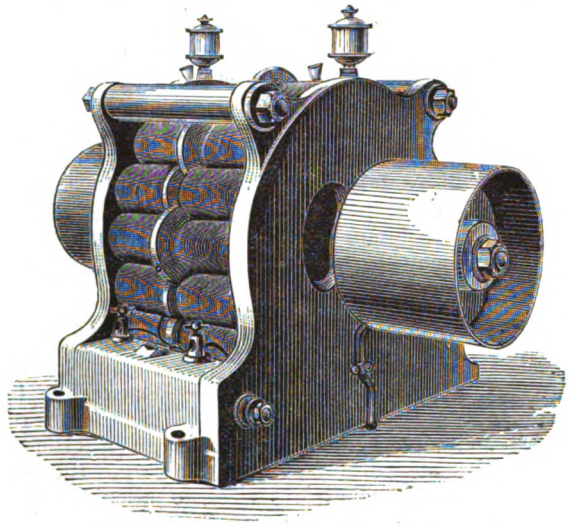

Fig. 30.—The Ferranti 1,000-light Dynamo.

by overlapping insulated rims, each one to the one next to that diametrically opposite, and a connection brought round again at the hub to the next but one from that at which the outer rim started, then applying similar connections all round, the radii would all be connected in circuit, and a much higher electromotive force might be obtained. I am not aware that any disc so connected has yet been tried.

Some improvements have also been made in the Elphinstone-Vincent machine. The sections of the armature of this

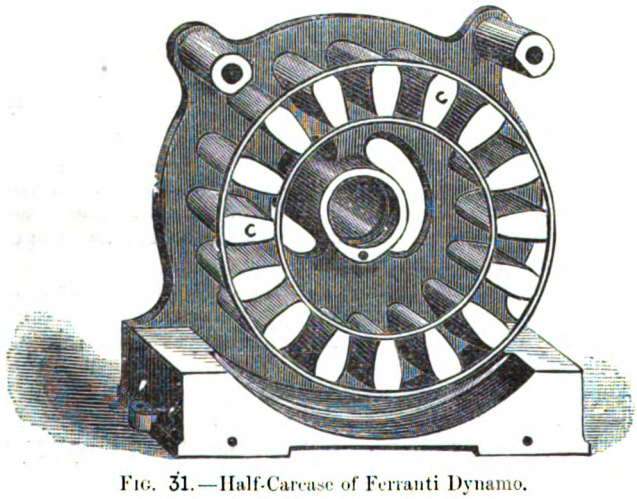

Fig. 31.—Half-Carcase of Ferranti Dynamo.

machine are wound separately in parallelogram forms like that shown in Fig. 29,* and the separate sections are then fixed upon the periphery of a papier-mache cylinder which is mounted so as to rotate between powerful field-magnets and internal field-magnets whose poles reinforce the field. In the improved machines the parallelograms of wire are so arranged that the overlapping ends lie outside the ends of the polar surfaces of the field-magnets, which, therefore, can be brought very close to the surface of the rotating cylinder. Amongst other improvements, also, segments of the collector are internally cross-connected, so that only two brushes are needed instead of six as formerly. Several improvements in mechanical details have also been made.

In alternate current machines something has also been done. The Ferranti-Thomson machine, which at the day of my Cantor Lectures had just made its appearance, has been considerably perfected. By the courtesy of Mr. Hammond I am enabled to show Figs. 30 to 33, illustrative of the "1,000-light" dynamo, and of its working parts. Externally the machine is scarcely charged at all, the driving pulley being a little larger in proportion. Internally considerable changes have

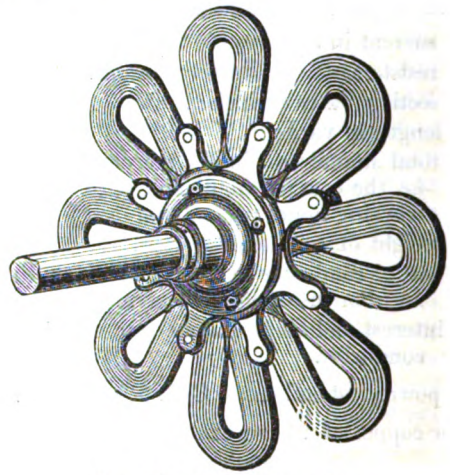

Fig. 32.—Ferranti Armature.

been made, and in these the hand of the experienced mechanical engineer is apparent. The framework of the machine is now cast in two halves, which are afterwards bolted together. Fig. 31 shows one-half of the carcase of the machine with its projecting circle of magnet cores C, which receive the field-

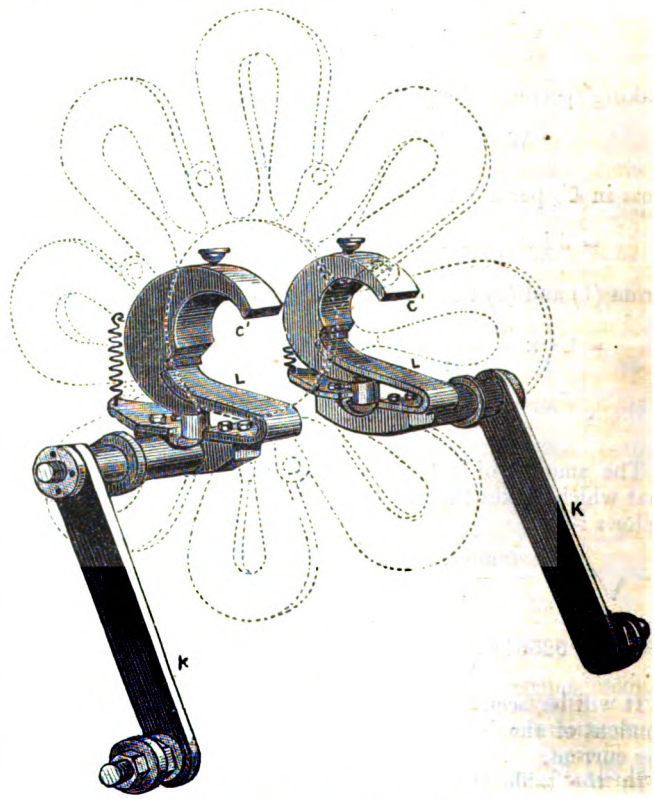

Fig. 33.—Collectors of Ferranti Dynamo.

magnet coils. The armature, originally a single zigzag piece of copper, has assumed the form shown in Fig. 32, in which it may be seen that the convolutions are multiplied, and are held in their places by bolts through a star shaped piece of brass,

* For illustrations of the Elphinstone-Vincent machine see *Electrician*, Vol. X., p. 233, Vol. XII., p. 113.

Digitized by Google

which also serves to carry to one of the two collectors the connection with one of the zigzag copper strips. There are in fact three complete circuits of copper strips in the armature connected in parallel arc. They begin at three of the alternate four bolts of the star-shaped piece, and, folding round one another, they all eventually unite with a second and inner star-shaped piece, which communicates with the second collector. Each strip makes ten turns round the zigzags, so that there are thirty layers, all well insulated from one another by strips of vulcanised fibre. This armature is 30in. in diameter, and a little more than ½in. thick in the upper convolutions, so that the opposite poles of the field-magnets can be brought very close together, and a very powerful field produced. The entire armature weighs only 96 pounds. The most extraordinary part of the machine is, however, the arrangement adopted for conveying the currents to the external circuit. The axle carries on either side of the armature an insulated collector ring of bronze, to which the aforementioned star-shaped pieces are respectively connected. Instead of brushes, solid pieces of metal, shown at C′ C′, Fig. 33, are employed to collect the current. These collectors hook on over the collecting rings, and bear against about 180° of the periphery of each ring. They are fixed on universal joints, and held by springs from rotating. Copper strips connect them to the terminals of the machine. The arrangements for lubricating the bearings are extremely perfect. The machine requires a speed of 1,400, and weighs 1½ ton. Mr. Ferranti has also designed a slow-speed dynamo to run at 300 revolutions per minute, and feed 500 lamps.

A very large alternate current machine was shown at the late Electrical Exhibition at Vienna by Messrs. Ganz, of Buda-Pesth. It was capable of furnishing light for 1,200 Swan

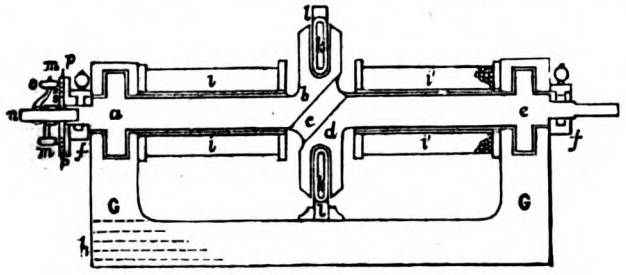

Fig. 34.—Sir C. Bright's suggested dynamo.

lamps (20 candle-power each). This dynamo, which in some points resembled Gordon's well known machine, was constructed according to the Mechwart-Zippernowsky system. The thirty-six bobbins of the field magnet were set concentrically on an iron frame, and rotated within an outer circle of thirty-six armature bobbins. The field magnet coils were, in fact, the fly-wheel of the high-pressure compound engine which drive the machine and its exciter. The diameter of the rotating part was 2½ metres. A salient feature of this machine is the fact that any one of the coils, either of armature or field-magnets, can be removed from the side of the machine in case such are needed. The whole fly-wheel can, in this way, be taken down by one man in a few minutes. An electrical efficiency of 85 per cent. is claimed for this machine.

Of one other class of machines—the unipolar dynamo—I had intended to say something. It is a remarkable thing that, though to my knowledge a great deal of attention has been paid lately to machines of this type, no one has yet succeeded in designing a practical unipolar dynamo. There seems to be some hiatus in the theory of this class of machine, for the very singular fact remains that those which are designed in defiance of precautions to avoid wasteful internal eddy currents will work, though badly, and those designed with such precautions will hardly work at all.

There are two or three other new designs for machines which at present can hardly be called anything but curiosities. There is, for example, a design for a dynamo (a drawing of which is given in Fig. 34) by Sir Charles Bright, in which the field-magnet coils and armature stand still, but in which the iron cores and the brushes rotate. There is another design by Professor G. Forbes, in which part of the field-magnets rotate. Mr. C. Lever has designed a machine on somewhat similar principles to the foregoing. I have myself essayed an alternate-current machine, in which both armature and field-magnets stand still, while laminated pole-pieces alone revolve. I hear also of a dynamo designed in the States, in which there are no field-magnets, only two revolving armatures.

And now I have left myself no time to deal with the third branch of my subject, namely, the dynamo in its functions as a mechanical motor. In this branch also much progress has been made. If time permitted I would speak of the motors designed by Professors Ayrton and Perry, which are successful to a very remarkable degree in yielding a great mechanical power in proportion to their weight. I might have been inclined to say something of the attempts made by the same able electricians to produce a self-governing motor by various devices of centrifugal and periodic governors, and also by using an ingenious differential winding. I might tell you how I have myself worked at the question from a different point of view, and have sought to govern motors so that they shall run at a uniform speed, by devices which will not wait until the speed changes before they act, but by devices depending upon the variations in the load of the machine, in short, upon dynamometric governors instead of centrifugal ones. These things must, however, wait until some more convenient season. Time will only admit of my showing you here, in conclusion, a model designed by Mr. C. Dorman to illustrate the graphic law of efficiency of motors, which I put forward in my Cantor Lectures, and which I am happy to learn has since been largely used in many different countries.

To sum up then, it may be observed that in every department under review the story of the past fifteen months is one of solid progress. It has been, it is true, progress of a quiet and perhaps of a commercial rather than a scientific order, yet, as I have shown you, one in which practice and theory have gone hand in hand. It is true that in some few points theory is ahead of practice, but in a still larger number practice is ahead of theory. It would be a great boon to us if our theoreticians could bring up theory to the level of practice in some of the simplest facts. We do not even know the exact law of the saturation of iron in electro-magnets, and content ourselves with formulæ, which we *know* to be incorrect. Of the laws of induction of magnetism in circuits partly consisting of iron, partly of strata of air, or of copper wire, we know very little. We want some new philosopher to do for the magnetic circuit what Dr. Ohm did for the voltaic circuit fifty years ago. There is ample room for progress yet in theory as well as in practice; and the perfection of theory means the deliverance of practice from arbitrary rules of thumb, and from the blunders of inexperience which have so retarded progress in the past. The history of the past fifteen months, however, gives great encouragement for the future, because it shows how much may be done, even in the face of great commercial depression, by those whose knowledge and experience give them a deliberate faith in the future, and whose efforts are directed toward no uncertain end. A steady development toward the yet far distant goal of perfection is going on unceasingly. The progress of which I am permitted to be the chronicler to-night is progress of the good and substantial kind, that owes nothing to the excited rush of Stock Exchange speculations, and which, not having been nurtured at an unhealthy fever heat, is destined to be of permanent value.

---

The Telegraph in Canada.—It is reported that the question as to whether the powers granted to the Canadian Pacific Railway Company enabled that company to do general telegraph business has been discussed by the Canadian Ministry. The Canadian Pacific Railway Company claim that in addition to their powers and franchises as a railway company they are also a telegraph company, without restriction as to amalgamation and leasing, and can do business all over the Dominion without the limitation as to rates enforced by Parliament on the regular telegraph companies. If these powers are as ample as claimed, other telegraph interests may be seriously imperilled. The Government by its large subsidies to the Canadian Pacific Railway Company will be contributing towards the practical confiscation of existing telegraph property in Canada by the competition which the Canadian Pacific could thus carry on. Moreover, as their property is exempt from taxation, while that of the other telegraph companies is taxable, they would have the advantage.—*N. Y. Elec. Review.*

## A HISTORY OF ELECTRIC TELEGRAPHY TO THE YEAR 1837.

BY J. J. FAHIE, MEMB. SOC. TEL. ENGS. AND ELECS.*

### CHAPTER VII.

(CONTINUED FROM PAGE 500.)

"At the central station in the Physical Cabinet a commutator is placed, which enables us by simple transpositions to effect the following changes in the wires and apparatus:—

"(1) The currents emanating at the central station traverse the receiving instruments of both the Bogenhausen and Lerchenstrasse stations at the same time.

"(2) The currents traverse the Lerchenstrasse line and instrument only, and the Bogenhausen line is connected through the receiving instrument of the central station, so that while one attendant at the latter station is *sending to* Lerchenstrasse, another attendant may be *receiving from* Bogenhausen.

"(3) Is the reverse of the last-named arrangement.

"(4) Bogenhausen and Lerchenstrasse are joined direct, and the apparatus at the Physical Cabinet cut out of circuit altogether.

"We have said before that at every half turn of the fly-bar from (say) *right to left*, one of the magnets of the indicator is deflected. Now we have so connected the apparatus that every time this movement takes place the high-toned bell should be struck, if the receiver be arranged as an acoustic instrument; or the corresponding beak shall print a dot on the paper strip, if the receiver be arranged as a recording instrument. On turning the fly-bar from *left to right*, the low-toned bell sounds, or the corresponding beak prints a dot, not upon the same line as the first, but on a lower one. High tones therefore correspond with the dots on the upper line, and low tones with the dots on the lower line, as in a musical score.

"As long as the intervals between the sounds or the signs remain equal, the said sounds or signs are to be read together as one signal, a longer interval indicates the completion of a letter or signal. We are thus enabled by appropriately selected groups to represent all the letters of the alphabet, or stenographic characters, and thereby to repeat and render permanent at all parts of the chain, where an apparatus like that above described is inserted, any information that we choose. The alphabet that I have chosen represents the letters that occur the oftenest in German by the simplest signs. By the similarity of shape between these signs and that of the Roman letters, they become impressed upon the memory without difficulty.

"Messages were printed with this apparatus at the rate of ninety-two words in a quarter of an hour, or over six words per minute."

*Discovery of the Earth Circuit.*

In order not to interrupt the continuity of our description of Steinheil's beautiful apparatus, we have reserved for a special paragraph our notice of this most important discovery.

As we have seen in our second, third, fourth, and fifth chapters, the earth circuit was used, with few exceptions, in all experiments with static electricity. Its function, however, was either unsuspected or misunderstood.† Of all the telegraphic proposals based on static electricity, those of Bozolus, 1767, and of the anonymous Frenchman, 1782, are the only ones in which complete metallic circuits were proposed. Reusser, 1794, used one common return wire; while all the others employed the earth, Volta, Cavallo, and Salvá making distinct mention of their doing so.

The power of the earth to complete the circuit for dynamic electricity has also been known for a very long time. Thus, on the 27th of February, 1803, Aldini sent a current from a battery of eighty silver and zinc plates from the West Mole of Calais harbour to Fort Rouge through a wire supported on the masts of boats, and made it return through 200 feet of intervening water.‡

Basse, of Hamel, made similar experiments, and about the same time, on the frozen water of the ditch, or moat, surrounding that town. He suspended 500 feet of wire on fir posts, at a height of six feet above the surface of the ice, then making two holes in the ice and dipping into them the ends of the wire, in the circuit of which were included a galvanic battery and a suitable electroscope, he found that the current circulated freely. Similar experiments were made in the Weser; then with two wells, 21 feet deep, and 200 feet apart; and, lastly, across a meadow 3,000 feet wide. Whenever the ground was dry it was only necessary to wet it in order to feel a shock sent through an insulated wire from the distant battery. Erman, of Berlin, in 1803, and Sömmerring, of Munich, in 1811, performed like experiments, the one in the water of the Havel, and the other along the river Isar.§

All these are very early and very striking instances of the use of the earth circuit for dynamic electricity; but the most surprising and apposite instance of all has yet to be mentioned, in which the use of the earth is suggested precisely as we employ it to-day. In a letter signed "Corpusculum," and dated December 8, 1837, in the *Mechanics' Magazine*,* we read:—

"It seems many persons have formed designs for telegraphs. I, too, formed mine, and prepared a specification of it five years ago, and that included the plan of making one wire only serve for the returning wire for all the rest, as in Alexander's telegraph; *but even that might, I think, be dispensed with where a good discharging train, as gas, or water, pipes, at each end of the telegraph could be obtained.*"

In July, 1838, or seven months after the publication of "Corpusculum's" letter, Steinheil made his *accidental* discovery in a way which we find thus related by De la Rive†:—

"Gauss having suggested the idea that the two rails of a railway might be employed as conductors for the electric telegraph, Steinheil, in 1838, tried the experiment on the railroad from Nüremburg to Fürth, but was unable to obtain an insulation of the rails sufficiently perfect for the current to reach from one station to the other. The great conductibility, with which he remarked that the earth was endowed, caused him to presume that it would be possible to employ it instead of the return wire. The trials that he made in order to prove the accuracy of this conclusion were followed by complete success; and he then introduced into electric telegraphy one of its greatest improvements."

In Steinheil's own account of this discovery, he begins by pointing out that Ampère required for his telegraphic proposal more than sixty line wires; that Sömmerring reduced the number to thirty or so; Cooke and Wheatstone to five; and Schilling, Gauss, and Morse to "one single wire running to the distant station and back."

He then goes on to say:—"One might imagine that this part of the arrangement could not be further simplified; such, however, is by no means the case. I have found that even the half of this length of wire may be dispensed with, and that, with certain precautions, its place is supplied by the ground itself. We know in theory that the conducting powers of the ground and of water are very small compared with that of the metals, especially copper. It seems, however, to have been previously overlooked that we have it within our reach to make a perfectly good conductor out of water, or any other of the so-called semi-conductors.

"All that is required is that the surface that its section presents should be as much greater than that of the metal as its conducting power is less. In that case the resistance offered by the semi-conductor will equal that of the perfect conductor; and as we can make conductors of the ground of any size we please, simply by adapting to the ends of the wires plates presenting a sufficient surface of contact, it is evident that we can diminish the resistance offered by the ground or water to any extent we like. We can, indeed, so reduce this resistance as to make it quite insensible when compared to that offered by a metallic wire, so that not only is half the wire circuit spared, but even the resistance that such a circuit would present is diminished by one half.

§ Gilbert's *Ann. der Physik*, Vol. XIV., pp. 26 and 385; and Hamel's *Historical Account*, &c., p. 17 of Cooke's reprint. Fechner, of Leipsic, after referring to Basse's and Erman's experiments in his *Lehrbuch des Galvanismus* (p. 268), goes on to explain the conductibility of the earth in accordance with Ohm's laws. As he immediately after alludes to the proposals for electric telegraphs, he has sometimes been credited with the knowledge of the fact that the earth could be used to complete the circuit in such cases. This, however, is not the fact, as we learn from a letter which Fechner addressed to Professor Zetzsche on the 19th February, 1872 (Zetzsche's *Geschichte der Elektrischen Telegraphie*, p. 19).

## THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

### INAUGURAL ADDRESS.

Delivered by Professor W. GRYLLS ADAMS, F.R.S., 10th Jan., 1884.

(CONTINUED FROM PAGE 502.)

It would appear, then, from these results that even in the early days of gas engines each of these gas engines is superior in practical efficiency to the very best steam engines.

It must also be taken into consideration that probably the gas used at the Crystal Palace was not of sufficiently good quality to yield 12,500 heat units per lb. on consumption, in which case these estimates of efficiency are too low.

Experiments were made with both the Otto and the Clerk engines with different quantities of gas, and also with different loads on the dynamometer. In working with the Otto 16 horse-power engine with a full load it was found that after some time the cylinder became so hot that no

Digitized by Google

flame was required to inflame the gas. A series of diagrams was taken with no gas jet to explode the gas, the explosion being caused by the heat of the cylinder when the unexploded gases were compressed by the piston. Fig. 1 (*a*) shows the character of the indicator diagram under these circumstances.

The Clerk engine was worked with a medium load and also with a light

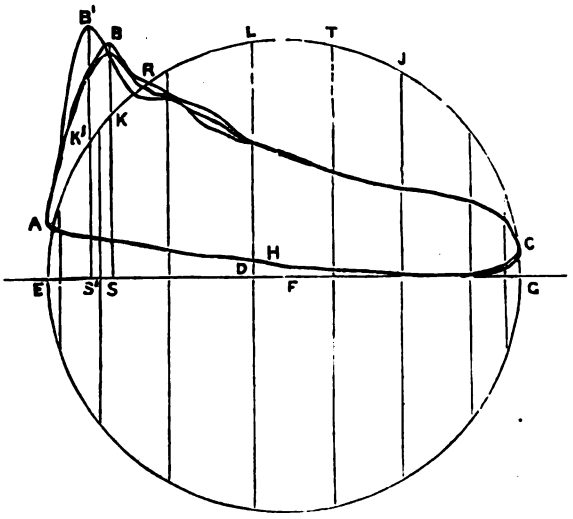

FIG. 1.

load, and Fig. 2 (*a*) shows the form of the indicator diagram when there is an explosion at every revolution with a light load.

The indicator diagram for the displacer cylinder with a full load is given in Fig. 3 (*a*).

The Froude absorption dynamometer employed in these experiments was kindly lent, and its working was superintended during the experiments by Mr. R. H. Froude.

The available horse-power in the Otto gas engine and in the Clerk engine have been calculated from the indicator diagrams, of which specimens are given in Figs. 1 and 2.

gas engines, which have been drawn from the consideration of a great many indicator diagrams, taken under different conditions :—

The pressure curve almost coincides with the isentropic line of gases.

With perfect ignition the rate of increase of pressure is very nearly uniform up to the maximum, which is reached in about the one-thirtieth of a second.

That the maximum pressures obtained in successive strokes are not the same, nor the times required for the maximum.

That the latter halves of the pressure curves are identical, provided the

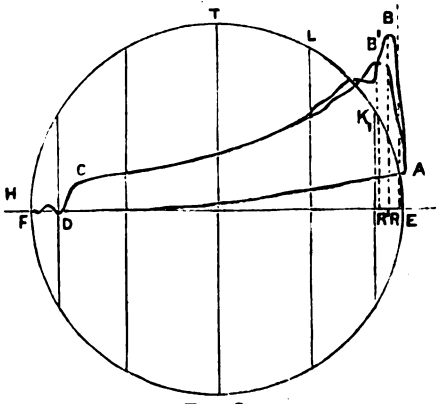

FIG. 2.

maximum pressure is reached at any time during the first half of the stroke. This is the case whether the explosion takes place promptly or slowly.

That the greatest amount of work is done when the maximum pressure is reached at the beginning of the stroke.

That, with a very hot cylinder, the heat developed on compressing the gases may be sufficient to cause the explosion without a flame to fire the gases, and that even the greatest pressure may be reached before the return stroke is finished.

That the greatest pressure reached in large and small engines is practically the same (considering the amount of compression), but that the time of reaching the greatest pressure is somewhat less in small engines than in large ones.

With higher compression of the gases before ignition, the maximum

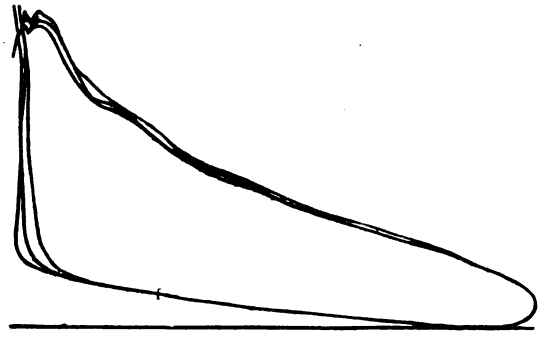

FIG. 1A.

FIG. 2A.

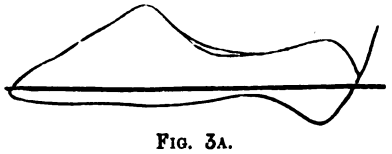

FIG. 3A.

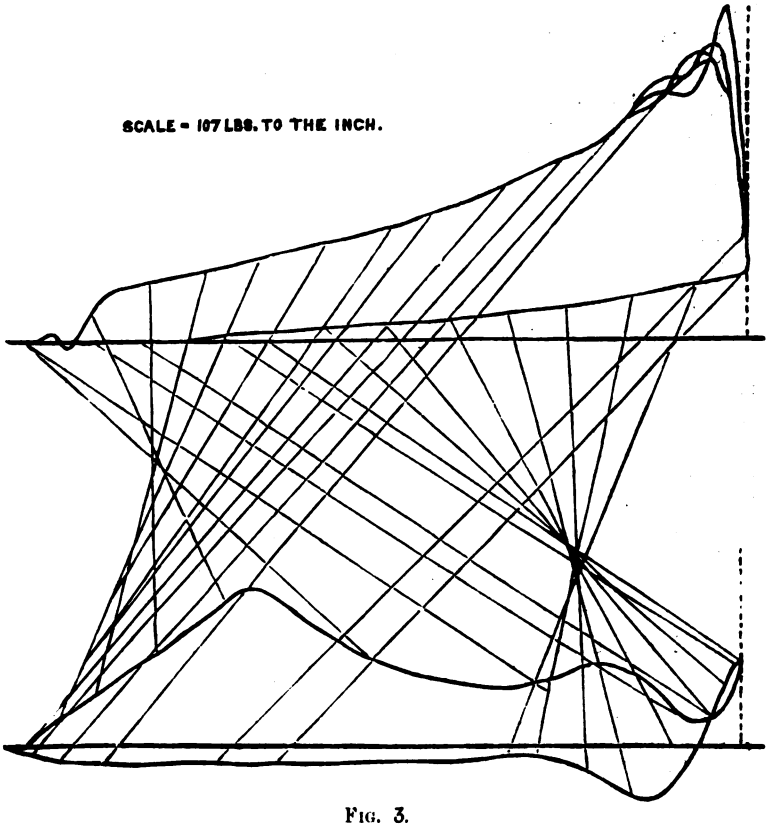

FIG. 3.

In these figures the circle shows the motion of the crank pin, and the distances between the ordinates are approximately the distances described in equal times by the piston. The periods of explosion, expansion, exhaust, indraught, and compression can readily be obtained from the figures.

Fig. 3 is a diagram (drawn by Mr. J. T. Sprague) to show the relative positions of the piston and the relative pressures at the same instant in the explosion cylinder and in the displacer cylinder of Clerk's gas engine at different parts of the stroke.

The following are the general conclusions with regard to the working of

pressures are increased, and the efficiency of the engine is greatly increased.

A considerable amount of loss of energy may arise from not carrying the expansion far enough before discharging the exploded gases. In the Clerk engine, especially, these gases were discharged at too high a pressure and temperature. The higher compression, which is practicable on account of the greater number of explosions in a given time in this engine, should greatly add to its efficiency. The engine works far more regularly in consequence of having an explosion at every revolution.

Digitized by Google

The results of the tests and the form of the indicator diagrams agree best with the theory that in gas engines dissociation takes place in the cylinder, and the pressure is kept up by continued combustion of the gases as the temperature falls.

It was found that from the beginning of the rise of pressure to the time of reaching the maximum pressure, except in certain special experiments when different quantities of gas were used, the interval was scarcely ever more than one-thirtieth of a second, and was often not more than one-fiftieth of a second. In exceptional cases the ignitions took place very late in the stroke, and the maximum pressures obtained were very much reduced.

In all the experiments with Crossley's Otto engine (whether large or small), the maximum pressures were higher as the time of reaching the maximum was diminished.

(TO BE CONTINUED.)

## FAURE ELECTRIC ACCUMULATOR COMPANY.

A meeting of the shareholders in this company, convened by circular sent out by Mr. Harcourt Turner, was held at the City Terminus Hotel, Cannon-street, on the 7th inst.

Mr. TURNER, who presided, said that since he issued his circular he had had an opportunity of examining the books of the Company to a certain extent. By the Articles of Association, M. Philippart, having become a bankrupt, had ceased to be a director of the Company. M. Cadiot had also sent in his resignation. The Company was therefore in this position—that it had only two directors, both of whom resided in France, and neither of whom, he understood, could speak a word of English. The assets of the Company were, he feared, in a very unsatisfactory state. The balance at the bank on the previous Thursday was only between £2 and £3. There was no doubt, however, that they had a claim against the French Electrical Storage Company for some calls, but he saw that morning that a petition had been filed for the winding up of that company before the Vice-Chancellor. It therefore occurred to him that the best thing to be done under the circumstances was to adjourn the present meeting, appoint a committee to investigate the affairs of the Company, and let that committee issue a report to the shareholders, at the same time asking them to meet at some future day to discuss the affairs of the Company and determine what steps should be taken in the future. He ought to remind the shareholders that the directors had called a meeting for Wednesday week, and he hoped that nothing would be said on the present occasion to prejudice that meeting.

Sir ARTHUR OTWAY, M.P., said that although he had had no communication whatever with the directors of the Storage Company since 1882, or with anybody concerned with the Faure Company, it had come to his knowledge indirectly that this Company was not altogether without hope of rehabilitating itself to a certain extent in regard to the property now in France. The French laws differed from the English in this important respect, that they afforded better facilities to *bonâ fide* creditors in realising their property, and he thought it would be prudent, in the interests of the shareholders, not to take any step now which would justify the French directors in refusing to come over here to attend the meeting on Wednesday week and give whatever explanation they were prepared with as to the Company's assets and other matters. The directors ought to appear upon that day and give explanations. If they did not, then he thought the shareholders of the Company would be in a stronger position to adopt what policy they chose than they would be if they approached the discussion of the Company's affairs before the meeting called by the French directors had taken place.

After a brief discussion this suggestion met with the approval of the meeting.

The following gentlemen were then appointed a committee of investigation :—Sir Charles Clifford, Mr. Edward Ponsonby, Mr. W. D'Oyley, Mr. Harcourt Turner, Mr. H. Rankin, Mr. L. A. Salamon, Mr. Grenfell, and Mr. W. W. Duncan. It was further decided that the committee should meantime take no steps calculated to interfere with the holding of the meeting summoned by the French directors, and that they should, by the issue of a circular, arrange for a large meeting of the shareholders to be held immediately afterwards.

The proceedings then terminated.

## THE EASTERN ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held yesterday at the Cannon-street Hotel, Mr. Ernest Noel, M.P., in the chair.

The CHAIRMAN said: Gentlemen, as you are aware, I was not here on the last occasion owing to a severe cold, and as you are aware also, the meeting was adjourned to this day to enable us to see Mr. Bull, one of our largest shareholders, who has been lately at Bombay. As he only returned last night, or yesterday, and I have only been able to see him this morning, it is quite impossible for the Board to lay before you those proposals that he thinks we shall be able to make, and therefore I shall simply move to-day that this meeting be and is hereby adjourned to Tuesday, the 22nd day of April, at the offices of the Company, 19, Great Winchester-street. As there are unfortunately so few of our shareholders who attend, we had much better have our meeting in our own rooms and save the expense of hiring a room. On that day, if all is well, Mr. Bull will have fully communicated with the Board all his views, he will then have given full information of the position of affairs at Bombay, and we shall be able to lay before you the reasons there are for or against the original proposal, and also as to what we may decide as to the future working of the Company.

Mr. JAMES PENDER seconded the motion, which was carried, and the meeting then separated.

## THE HAMMOND ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).

The third ordinary general meeting of the Hammond Electric Light and Power Supply Company (Limited) will be held at the works of the Company, Appold-street, Finsbury, on Thursday, 17th April, at 12 o'clock noon, for the purpose of receiving the report of the directors and accounts for the year 1883, the election of auditors for the ensuing year, and for the transaction of any other business that may be necessary. Upon the termination of the meeting, an extraordinary general meeting of the shareholders will be held at the same place, at which the following resolutions will be proposed :—1 "That the nominal capital of the Company, which now consists of the sum of £330,000, divided into 66,000 shares of £5 each, be increased to the sum of £525,000, and that this amount be divided into 350,000 shares of the nominal value of £1 10s. each." 2. "That 50,123 shares of the nominal value of £1 10s. each, forming part of the said capital of £525,000, be issued as fully paid up, and that the same be applied in manner following, that is to say :—(*a*) 40,133 of the said £1 10s. shares rateably to the present holders of the 40,133 ordinary £5 shares in this Company ; (*b*) 7,990 of the said £1 10s. shares to the holders of the 15,980 deferred £5 shares in this Company, and 2,000 of the said £1 10s, shares to the holder of the founder's shares in this Company." 3. "That the directors be empowered to enter into such agreements or contracts as may be necessary for the carrying out of all or any of these special resolutions, and to issue and allot the balance of the authorised nominal capital of the Company from time to time, on such terms and conditions as they in their discretion may think fit." 4. "That an indenture bearing date the 19th day of March, 1884, and made between the Hammond Electric Light and Power Supply Company (Limited), of the one part, and Robert Hammond of the other part, be and the same is hereby ratified and confirmed."

SUBMARINE CABLES TRUST.

NOTICE IS HEREBY GIVEN, that the COUPONS of the Submarine Cables Trust, due on the 15th INST., will be PAID on and after that date by Messrs. Glyn, Mills, and Co., at 67, Lombard-street, E.C., between the hours of 10 a.m. and 2 p.m. The Coupons must be left for examination three days previous to calling for payment.

LEWIS WELLS,
Secretary.

No. 66, Old Broad-street, April 7, 1884.

MR. ROBERT HAMMOND on THE ELECTRIC LIGHT IN OUR HOMES.

Mr. Hammond will LECTURE at ST. JAMES'S HALL on this subject at Eight o'clock on WEDNESDAY EVENING, the 16th April.

A Drawing Room will be Illuminated with Incandescent Lamps.

Stalls, 5s. ; Balcony, 3s. ; Area, 2s. ; Admission, 1s. Tickets can be had from Mr. Austin, at St. James's Hall ; and from all the West End and City Libraries.

GILBERT HARRISON & CO., Telegraph Engineers, 1, ST. SWITHIN'S LANE, E.C. Contractors for all kinds of ELECTRIC BELL Work, Speaking Tubes, Lightning Conductors, &c. Sole proprietors of the "STEWART" ELECTRIC INDICATOR, the most effective made.—N.B. A new Voltaic Battery, possessing some extraordinary features, and eminently adapted for Incandescent Lamps, will shortly be placed before the public by the same proprietors, GILBERT HARRISON & CO., 1, St. Swithin's-lane, E.C.

JUST PUBLISHED.

## NOTES.

CABLES INTERRUPTED.—The following cables are interrupted, viz. :—Rio Grand do Sul-Monte Video, and Trinidad-Demerara.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended April 11 amounted to £3,348.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending April 11, 1884, were £2,610.

CONSOLIDATED TELEPHONE CONSTRUCTION COMPANY.—This company have received a gold medal for their exhibits at the Calcutta Exhibition.

EARTHQUAKES IN TASMANIA.—The latest news from Tasmania states that shocks of earthquake continue to be felt in the north. Though some were heavy they attracted little attention.

LECTURE.—On Wednesday evening Mr. Robert Hammond delivered an interesting lecture at St. James's Hall, Piccadilly, on "The Electric Light in Houses," to a large and appreciative audience.

SOCIETY OF TELEGRAPH ENGINEERS.—Mr. Blacksley's paper on conductors, which was to have been read at the last meeting of this society, is announced for the meeting on Thursday next.

CABLES REPAIRED.—The following cables have been repaired, viz. :—Orkney-Shetland, Falmouth-Bilbao, and Mollendo-Chorillos. Telegraphic communication with the island of Islay (Scotland) has also been restored.

PERSONAL.—Messrs. Woodhouse and Rawson have secured the services of Mr. W. L. Magden (late district manager in Ulster of the National Telephone Company) as manager of their electrical supply department in London.

ELECTRIC LIGHTING IN THE HOUSE OF COMMONS.—The electric light in the House of Commons has proved so satis factory, says the *Daily News*, that it is the intention of the authorities to have it extended to all parts of the building.

CUBAN TELEGRAPHS.—A Reuter's telegram from New York, dated April 10, says :—"A despatch from Havana states that the Cuban authorities have re-established the censorships of telegraphic news messages despatched to and from the island."

DEATH OF ROBERT GRIMSTON.—The Hon. Robert Grimston, fourth son of the first Earl of Verulum, and formerly the chairman of the Electric and International Telegraph Company, died suddenly at Gorhambury, on Monday, 8th inst., in his 68th year.

EARTHQUAKE IN ITALY.—A strong shock of earthquake was felt at Urbino at a few minutes before eight o'clock on the morning of Thursday, the 10th inst. Its duration was five seconds. A shock was also felt at Belpasso in Catania at 9:25 a.m. on the same day. No damage was done.

THE SENEGAL CABLE.—It is probable that the Canary Islands-Senegal cable will be completed in a few days by the ss. "Dacia," belonging to the India Rubber, Gutta Percha, and Telegraph Works Company. This cable completes the last link between Cadiz and Senegal *viâ* the Canaries.

OVERHEAD WIRES.—The Paddington Vestry is of opinion that telephone wires should only be laid with the consent of the Metropolitan Board of Works, and that works to be done by telephone companies should be carried out to the satisfaction of the vestries and district boards of the metropolis.

MR. A. RECKENZAUN.—We learn that Mr. A. Reckenzaun, who has for some time been engineer to the Electrical Power Storage Company, of Millwall, is about to leave this company and to devote himself entirely to the electric transmission of power, and to the application of electricity to engineering purposes in general.

AN AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—It has been proposed to start an institute under this title in New York. A number of well-known electricians and others have subscribed themselves as members. Further information concerning the institute is to be had of Mr. N. S. Keith, of 237, Broadway, New York.

ORIENTAL TELEPHONE COMPANY.—Subject to final audit, the directors of the Oriental Telephone Company will, at the annual general meeting which it is intended to hold on the 30th inst., recommend a dividend at the rate of 5 per cent. per annum on the ordinary shares of the company for the year ending 31st December, 1883.

BALLOONS FOR WAR PURPOSES.—Extensive experiments are to be made by the military authorities during the coming summer as to the use of balloons for war purposes. A number of men are to be instructed at Chatham in the manufacture of gas, &c., and also in telegraphy, photography, and electric lighting, for signalling purposes.

ELECTRIC LIGHTING IN EDINBURGH.—The furniture warehouses of Messrs. John Mitchell and Son, of 106, Prince's-street, Edinburgh, are now lighted by incandescent lamps. The current is supplied by secondary batteries, which are charged by a Higgs self-regulating dynamo. The installation has been carried out by the firm of Paget Higgs (Limited).

ELECTRIC LIGHTING IN BRUSSELS.—It has been decided to light the Grand Place, Brussels, by electric light. The Town Council have invited inventors to make trial of their various systems, promising that the system which gives the best results shall be definitely adopted. The motive power, derived from a gas engine in the Maison du Roi, will be provided free of expense by the Town Council.

AMERICAN TELEGRAPHS.—The House Committee on Post Offices, which has been sitting at Washington to consider the advisability of the proposed purchase by the Government of the United States telegraphs, has declared itself adverse to the project. A resolution was passed to the effect that it was inexpedient for the Government either to construct a postal telegraph system or to purchase the existing lines.

ACCIDENT FROM LIGHTNING.—The *Colonies and India* says :—"A woman named Harriett Cleaver has been struck dead by lightning at Evans Creek, Stoney Pinch, near Mudgee, New South Wales. She had just covered up her sewing-machine, and had one of the needles in her hand when the electric fluid penetrated the slabs of the hut and killed her on the spot. The needle was twisted in all directions."

THE GULCHER COMPANY.—A petition for confirming the resolution recently passed by the shareholders of this company for reducing the capital from £300,000 to £150,000 was presented to Mr. Justice Pearson on the 3rd inst., and is now pending. The list of creditors of the company is to be made out as for the 19th May. Messrs. Davidson and Morriss, of 40, Queen Victoria-street, E.C., are the company's solicitors.

REUTER'S TELEGRAM COMPANY.—The directors of this company report that the net profits for the year ending 31st

Digitized by Google

December last amount to £5,858, including £92 brought forward from the last account. The usual interim dividend of 2½ per cent. was paid in October last, and the directors now declare a further dividend of 4s. per share, equal to 2½ per cent., making a total distribution of 5 per cent. for the year.

A Field Telephone.—During the march on Portsmouth of the volunteers a new portable field telephone, introduced by the London and Globe Telephone Company, was used to transmit messages from the main signalling station to the head-quarters of the officer commanding one of the columns. We believe that the instrument, which acted both as receiver and transmitter, did not answer quite so well as was expected.

The Victoria Dynamo.—One of this class of machines has lately been supplied by the Anglo-American Brush Electric Light Corporation to Colonel Festing, R.E., for use at the South Kensington Museum. This machine is capable of running 125 twenty candle-power lamps. It is compound wound, but may be used for charging the Faure-Sellon-Volckmar cells there, and will replace a smaller machine of the same type, which was supplied to Colonel Festing for the same purpose a year ago.

The Maxim-Weston Systems.—We are constantly reading in American technical periodicals of the large installations which are carried out by the United States Electric Lighting Company, who own the Weston and other patents, and it is a wonder to us that nothing is now heard of the Maxim-Weston systems in this country, more especially as Professor Maxim was said to have been retained at a high salary by the English company to establish a sound business. This had a business sound about it.

The Criterion Theatre.—This theatre was opened this week after having undergone considerable alterations and improvements. Among the latter may be reckoned the introduction of the electric light throughout, to the entire exclusion of gas. One consequence of the employment of the electric light will be that the delicate gilding and the satin upholstery will last three or four times as long as they would if gas were used. The lighting has been carried out by the Edison and Swan United Company, and we shall probably refer to it in greater detail in another issue.

The United States Patent Law.—The agitation for reform of the Patent Laws still continues in the United States. No less than twenty-eight Bills have been introduced into the present Congress which interfere more or less directly with patents or their owners, and diminish in one way or another the protection afforded to inventors. One Bill provides that no damages can be recovered for infringements prior to written notice served on the infringed by the patentee, thus rewarding the secret manufacture of patented articles. Another Bill is to prevent the recovery of damages in cases where the amount involved is less than 20 dollars, and another Bill fixes this amount at 50 dollars.

Indo-European Telegraph Company.—The report of this company states that the revenue from all sources for 1883 amounted to £100,065. Deducting the expenses, taking credit for £449, balance brought over from 1882, and debiting income-tax, there remains the sum of £44,903. From this amount, £10,625 paid for interim dividend, £5,000 placed to reserve, and £5,843 paid on account of the Persian debt, have to be deducted, leaving a balance of £23,434 available. The directors propose the declaration of a dividend for the last six months of 17s. 6d. per share, making, with the interim dividend already paid, 6 per cent. for the year, and a bonus of 10s. per share, making in all 8 per cent. for the year.

Electric Lighting in Works.—The works of Cail and Co., of Paris, have been partially lighted by electricity since 1876; but now a total area of 23,407 square metres, including the fitting and erecting shops, the drawing office, the general offices and stores, are electrically illuminated. The work has been entrusted to MM. Sautter et Lemonnier, of Paris, who have adopted the system of machines of low tension and great quantity, by arranging the lamps in subsidiary circuits. The four I D Gramme dynamos, making 700 revolutions a minute, have an electromotive force of 70 volts, and give a current of 280 amperes. Three of them supply respectively 22, 24, and 26 arc lamps, and the fourth 22 arc and 83 incandescent lamps. The engines give out 140 horse-power, of which the arc lamps absorb 1·38 horse-power, and the incandescent lamps 10 kilogram-metres, or 72¼ foot-pounds each. The whole plant costs 72,673f. = £2,907, while the expense per hour is 0·107f. for each arc lamp, and 0·01f. each incandescent lamp, without reckoning the motive power.

The Eastern Extension Telegraph Company.—According to the half-yearly report of the Eastern Extension Telegraph Company the gross receipts, inclusive of Government subsidies, amounted to £231,056, against £209,131 for the corresponding period of 1882. After deducting exceptionally heavy working expenses, amounting to £69,862, and interest on debentures and contributions to sinking funds, there remains a balance of £150,076, including £32,356 brought forward. It is proposed to pay another quarterly dividend of 1¼ per cent., with a bonus of 3s. per share, making, with the interim dividends and bonus paid for the first half of the year, a total distribution of 7 per cent. for 1883. The reserve fund now stands at £462,821. The report states that the directors have obtained a subsidy of £10,600 per annum from the French Government for providing and maintaining a cable between Cochin-China and Tonquin. They have also obtained a small subsidy from the Portuguese Government for connecting Macao with the company's system at Hong-Kong.

Great Northern Telegraph Company.—According to the statement of accounts of this company for the year 1883 the receipts from all sources amounted to £296,355. Of this sum £254,960 were derived from traffic receipts. The expenses for the year were £73,600. The chief items among the expenses were salaries and wages, £36,298; expenses of stations, &c., £9,767; supervision and maintenance of sea and land lines and repairing steamers (2), £9,480; instruments and cells, £2,376; bank commission, £2,544; and loss on exchanges, £11,133. Interest on debentures, &c., took £90,600. Out of the surplus it is proposed to declare an interim dividend of 5 per cent., and an extra dividend of 3 per cent., which will absorb between them £120,833. An addition of £55,555 is to be made to the reserve and renewal fund, £2,222 to the pension fund of the staff, £1,500 goes for directors' fees, and a balance of £25,644 is to be carried forward. The company's assets in the shape of cables and land lines with all appurtenances figure in the balance sheet at £2,016,593.

A New Switch.—The Anglo-American Brush Electric Light Corporation have lately brought out a patented converting switch, whereby a dynamo may be made to produce two different strengths of current by means of a simple and cheap contrivance fitted on to the dynamo shaft. The dynamo can be made to produce at will, in the case of the No. 7 Brush machine, 800 volts and 10 amperes, or 1,600 volts and 5 amperes. The same contrivance has been applied to a No. 8 Brush machine with most satisfactory results, and to all the large sizes, and has in several cases saved the cost of extra

Digitized by Google

plant, as machines fitted with this switch can be used for driving a series of arc lamps in the night time by means of a high tension current, and charge secondary batteries in the day time by means of one of lower tension. There has been a difficulty, chiefly mechanical, experienced in applying this most estimable contrivance to the smaller sized Brush machines, but this has been completely got over, and a small Brush machine fitted in this way has lately been supplied to the Australasian Electric Company in the form of a No. 4 machine to give 300 volts and 5 amperes, or 150 volts and 10 ampere.

ELECTRICAL POWER STORAGE COMPANY.—The ordinary general meeting of this company will be held at the Cannon-street Hotel on the 23rd instant. An extraordinary general meeting will also be held at the termination of the ordinary meeting, when the following resolution will be submitted as a resolution not requiring subsequent confirmation, viz. :—"That the capital of the company, which is now £800,000 divided into 400,000 shares of £2 each, of which 264,900 are in issue, and are fully paid, and 135,100 are unissued, be consolidated into 200,000 shares of £4 each, so that every holder of two shares of £2 each fully paid shall become the holder of one share of £4 fully paid, and the capital shall consist of 132,450 shares of £4 each fully paid, and 67,550 shares of £4 each unissued." In the event of the above resolution being passed, the following further resolution will be submitted as a special resolution requiring subsequent confirmation, viz. :—"That the capital of the company be reduced from £800,000 divided into 200,000 shares of £4 each to £200,000 divided into 200,000 shares of £1 each, and that such reduction be effected by reducing the nominal amount of every share from £4 to £1." The report of the company will be found in another column.

POST OFFICE EMPLOYES' INSTITUTE.—The East London Postal and Telegraph Employés' Circulating Library and Institute have just issued their annual report, from which it appears that during the period that has elapsed from the last general meeting of members in April, 1883, to the present, the work accomplished has necessitated hard and continuous efforts. This work has been the reorganisation and extension of the library, opened in April, 1878, for the postal and telegraph *employés* of the East London town and suburban districts, and the establishment, in connection with it, of an institute with various clubs and agencies for promoting the intellectual improvement and rational recreation of the various classes of officers, particularly the younger. The library consists of 4,000 volumes in all departments of literature, suitable for general readers, and has been entirely reorganised. It has for its centre the district office in the Commercial-road, from which, every two months, books in numbers proportionate to the staff employed are sent to the numerous branch offices. The extent to which the library has been appreciated may be found in the fact that 2,500 books have been taken out during the last two months at branch and suburban offices. Cricket, swimming, and athletic clubs form part of the work of the institute.

VOLK'S ELECTRICAL RAILWAY.—The visitors to Brighton during the Easter holidays have thoroughly tested the efficiency of the portion of the line already opened. We believe that on Easter Monday more than two thousand passengers were carried during the day. We find also that here, as in other new departures, a good deal of misapprehension exists in regard to the dangers involved in electrical transmission of power. A paragraph which appeared in our issue of April 5th relating to a telegram about the Portrush Railway has been by many misunderstood. We had no intention to do more than give a piece of peculiar news similar in character to that which is generally in vogue about any new thing which is appreciated by those who have some knowledge of the subject as pertaining to the character of a joke. We have had to disabuse the minds of some prominent and even eminent Brightonians as to the dangers of the electrical railway; in fact we have emphatically stated that no danger exists with regard to injury from accidental or wilful contact with the metals. Electricians will know when we say that the electromotive force used is under 150 volts that no danger can occur from such contact. Children—young and old—amuse themselves by touching both rails. We trust that the utility of this railway will soon commend itself to those who, even now, look upon it as a dangerous innovation.

ELECTRIC LIGHTING ON WAR SHIPS.—The Anglo-American Brush Electric Light Corporation have secured the contracts from the Admiralty for supplying and fitting up the electric light on the following ships of the Royal Navy, in addition to the "Colossus," which is making rapid progress towards completion, and which will be fitted up with the Brush Corporation's incandescent lights throughout, viz., the "Bacchante," "Raleigh," and "Conqueror." The apparatus to be fitted up comprises electric search and yard arm lights, with engines, dynamos, and cable for the same. To work these lamps the corporation are supplying their compound wound Victoria machines of the $E_2$ size, duplicate machines being supplied in each case. For driving the dynamos on board the ships "Conqueror" and "Raleigh" engines of the Brotherhood type will be used, while for the dynamos on the "Bacchante" Parson's direct acting high speed engines, as manufactured by Messrs. Kitson and Co., of Leeds, are to be employed. Each machine will be capable of supplying and maintaining at a speed of 400 revolutions 200 twenty candle-power incandescence lamps, or a single powerful search light. Reflecting lanterns, each fitted with eight 40 candle-power incandescence lamps for use in loading and unloading are also being supplied to each ship, the incandescence lamps to be used being those of this corporation's special design and make.

TELEGRAPH CODES.—In the case of Ager *v.* the Peninsular and Oriental Steam Navigation Company, the statement of claim set forth that the plaintiff, Dr. Ager, was the proprietor of copyright in the book "The Standard Telegram Code," which was published in 1879, and entered at Stationers' Hall under the Statute 5 and 6 Vict., c. 45. The book consisted of 100,000 words, from "Aafsch to Travail," which were selected from eight languages, and specially compiled for telegraphic transmission. The plaintiff complained that the defendants had printed a large number of copies of the book, and distributed them among their agents at home and abroad, and had thus prevented the plaintiff from selling many copies of his work. The action was for an injunction, an account of the copies printed, and for costs, and consequential relief.—The defence was that the defendants bought a copy of the above-named book, and compiled for their own use, with the aid of such book, a new and independent work, which was their own private telegraph code. They stated that their work was substantially different from the plaintiff's, and that they had distributed 60 copies of it among their agents. They further said that they had made such extracts from the plaintiff's book as were reasonable in quantity and quality, regard being had to the object with which the plaintiff's book was sold to the defendants. They had not printed the book for sale or exportation within the meaning of the Statute 5 and 6 Vict., cap 45, and they denied that they had done the plaintiff any damage.—Mr. Justice Kay gave judgment on Wednesday,

Digitized by Google

9th inst. After stating that the facts were peculiar, that the copyright was admitted, but the infringement denied, he said he had no doubt that enough of the plaintiff's book was copied to constitute a serious invasion of his rights, and the justification attempted by the defendants that they only gave their books to their agents "privately," and did not publish or otherwise use them, was not sufficient to enable them to multiply copies. He held that there had been a multiplying of copies of the plaintiff's book within the words of the Copyright Act, and that that was an invasion of the copyright against which the plaintiff was entitled to be protected; therefore judgment must be given for an injunction to prevent the printing or distributing of the defendants' copies, and those remaining on hand must be delivered up to the plaintiff, who was entitled to an inquiry whether he had suffered damages, and the defendants must pay all the costs of the action.

DEATH OF M. J. B. DUMAS.—M. Dumas, the celebrated chemist, died on Friday, the 11th inst., at Cannes, where he had gone to recruit his health. We take the following account of his life from a telegram to the *Daily Telegraph*:—"Jean Baptiste Dumas was born at Alais, in the Department of Gard, on July 14, 1800. Like Sir Humphrey Davy, he commenced his career of usefulness by the study of medical chemistry, in which he made such progress in his native town, and afterwards at Geneva, that he attracted the notice of Decandolle and Prévost. He became the pupil and afterwards the fellow-worker of the latter, in conjunction with whom he published some well-known works on physiological subjects. In 1821 he came to Paris, where he obtained a post at the Polytechnic School. Shortly after his arrival in the capital he married the daughter of Brongniart, the manager of the Sèvres manufactory, himself a chemist of considerable reputation. Through the influence of his father-in-law's patronage Dumas was soon pushed to the front rank of French scientists. He distinguished himself by his scientific disputations with Berzelius, who had controverted some of the theories advanced by Dumas in his 'Substitutions,' a work in which the latter had asserted and proved in a logical manner the unity of matter. Metallurgy next chiefly occupied his attention, and he also published several essays in practical chemistry, on the action of alkalies, on matter, on ether and its compounds, on indigo, on nitric acid, and on the means of preventing the destruction of vines by the phylloxera. As a professor of chemistry M. Dumas distinguished himself not only by his accurate and attractive scientific demonstrations, but by a fluency and elegance of style, both in his writings and lectures, which fascinated his readers and hearers. In 1832 he was elected a member of the Academy of Science, of which he was appointed permanent secretary in 1868, in succession to M. Flourens. Since 1843 he had been a member of the Academy of Medicine, and his fame having become universal the Faraday Medal was awarded to him in 1869 by the Chemical Society of London. On the death of M. Guizot, Dumas presented himself as a candidate for a seat among the academicians, but was unsuccessful. He was elected, however, in December, 1875, and took his place among the Immortals in June, 1876. In 1849 he assisted the Government in various legislative matters connected with coinage, the preparation of stamped paper, taxes on salt, sugar, and other things, in which his scientific knowledge proved itself invaluable. He entered Parliament for the Department of the Nord before the *Coup d'Etat*, and was soon after appointed Minister of Commerce and Agriculture. He became a senator in 1852, and filled several important public offices. In 1863 the Grand Cross of the Legion of Honour was conferred upon him. His principal works are 'Chemistry Applied to the Arts,' 'Lessons in Chemical Philosophy,' 'An Essay on the Chemical Statistics of Organic Bodies,' and other shorter treatises, which appeared at various periods of his long, useful, and laborious life. Among the most celebrated of the pupils of M. Dumas may be mentioned M. Pasteur, who has equalled, if not surpassed, his former master in renown."

TRINITY HOUSE EXPERIMENTS ON LIGHTS.—The *Standard* of the 12th inst. gives a long account of experiments conducted by the Trinity House authorities for testing the relative efficiency of gas, oil, and electricity for lighthouse purposes, from which we extract the following:—"On the hill behind the South Foreland High Lighthouse, in line with it to the north-west, three strong wooden towers have been constructed of 12in. timber framing, each having a weather-boarded room, about 16ft. square, and above this a lantern 21ft. high and 14ft. in diameter. The lanterns are all screened on the south, to prevent their lights from interfering with the proper duty of the South Foreland permanent lights. The beams from these temporary lighthouses emerge more or less eastwardly and westwardly, and show to seaward within certain bearings which have been indicated in an official notice to mariners recently issued, which has been advertised in our columns. The first of these towers is 245ft. from the permanent upper lighthouse, and the others are 180ft. apart. The first, or A tower, is devoted to electric lighting. Three De Meritens machines and three lamps of 30,000 candle-power each, capable of being raised to 60,000, are to be employed in it. The second, or B tower, has Mr. Wigham's quadriform gas apparatus and service lenses installed in it, the burners of each set being 48 for fine weather, rising to 68 and 88, to 108 for extreme bad weather. The third, or C tower, is adapted for mineral oil supply, and displays the Trinity House multiple ring burner in triform series, with long lenses like those in use at the new Eddystone lighthouse. The lantern of every tower is fitted on one side with single panels of a fixed refracting belt, representing apparatus in use for the fixed lights on our coasts. Revolving gear is applied to the optical apparatus in all three towers, and telephonic communication will be maintained between the towers and the committee's head-quarters and the three observing sheds and stations, which are placed at distances of 700, 2,000, and 4,325 yards along a line of pegs or range traced eastward to that extent. Whenever the lights from the towers are not visible to the shed stations, two of the men there on duty will walk towards the towers until the lights are sighted, and will note the distances at which each respectively becomes visible. The first series of trials was with single lights of each kind, through single sections of the ordinary Trinity House refracting rings, and upper and lower bands of prisms for fixed lights. A red screen was put to the electric light, and the precision of the division of the white light from the red shadow was perfect. Afterwards two lights in each system, both fixed and flashing, were tried; then three in the oil and gas; then three oil, four gas, and two electric, the condensed beams in the condensed flashes being marvellously fine as they turned into full focus upon the eye. It was now that the external scene reached its highest grandeur; enormous luminous beams curved through the sky, high above hill and hollow combe, and far away over the sea revolving they streamed around. The eminences of the rounded undulating ground caught streaks of brightness, and lit up in glowing white, orange, or yellow, as the revolving rays of carbon, gas, and oil fell upon them. The air was filled with huge, bright, and lurid beams, and with sombre shadows, whilst high above the electric lantern a tall column of intense

Digitized by Google

blackness rose like a funereal obelisk high into the sky. As one stood under the electric tower the light from its lantern appeared to illumine a vast shadowy dome in the air above, divided by ribs and bonds pencilled in more shadowy hues. Around the oil and gas towers the inverted images of their powerful lights were streaked out upon the ploughed fields; and over the gas tower the cloudy sky glowed with a deep red glow from the ex-focal rays of its optical lenses. From every lantern's interior walls volumes of reflected light poured forth. Observing from Cornhill on the west, the flashes from oil and gas seemed almost of equal brightness, and at times it was impossible to give the palm to one or to the other. The three oil lights at a closer distance had a distinct identity. But, except at a very close approach, the fusion of the gas rays could not be disintegrated, and the gas light had a superb manifestation such as only those who have seen the famous light on the coast of Cork can conceive. The Douglass oil light is a wonderful light; and it is marvellously well that its rays are caught and grouped and sent out in such splendid flashes. The experiments now begun will continue day by day for many months."

Speed on Cables and Landlines.—Mr. W. H. Finlay, F.R.A.S., Chief Assistant at the Royal Observatory, Cape of Good Hope, communicates the following paper on this subject to the April number of the *Journal* of the Society of Telegraph Engineers and of Electricians. He says:—"On my arrival at Lourenço Marques, in November, 1881, on my way back from Aden, I received a telegram from the Astronomer Royal at the Cape, asking me to make preliminary trials and arrangements for signals. In these I met with most cordial assistance from Messrs. Heraghty and Carlisle, telegraph superintendents at Lourenco Marques and Durban respectively. It was found impossible to use the mirror galvanometer between these stations, as a single cell sent the spot of light off the scale, so we determined to use the Morse, as in the ordinary working. The battery consisted of 10 Leclanché cells. The signals were exchanged on the night of November 4th, and the programme was as follows:—(1) Signals were sent from the Cape Observatory by Mr. Pett at intervals of 10 seconds for eight minutes, and the time of their arrival noted at Durban by Mr. Maclear; then signals were sent from Durban to Observatory for 15 minutes, and lastly signals again from Observatory to Durban for eight minutes. (2) A similar set of signals was interchanged between Durban and Lourenço Marques. (3) A Siemens relay was inserted between the cable and landline at Durban, and signals interchanged between Observatory and Lourenço Marques. At the Cape a sidereal clock was used, at Lourenço Marques a sidereal half-seconds chronometer, and at Durban a mean time clock, which had been put up there for the Cape Longitude Expedition. Now, a sidereal clock gains one second in six minutes approximately on a mean time clock, so that once in every six minutes the Observatory and Durban clocks would be beating together, and once in three minutes the Durban clock and Lourenço Marques chronometer. These coincidences were the phase observed in operations (1) and (2). In (3) the time of the signals being received had to be estimated to tenths of a second; but Mr. Pett and I have had long experience of such signals, and have always agreed (in the mean of several observations) in the subdivision of the seconds. The absolute errors of the clocks are of no importance for my present purpose, all that is wanted is their rates during the time of the signals. For the rates at the Cape and Durban I am indebted to Mr. Gill, Astronomer Royal at the Cape. The rate of my chronometer at Lourenço Marques I determined from observations there. The observations extended over a considerable part of the night, and I have not reduced all the signals to a common epoch; but each operation is complete in itself, *i.e.*, reduced for rate to its mean epoch. The only other point to be considered is the personal equation of the different observers in sending and receiving signals. All signals were sent in coincidence with the beats of the timepiece, and the accepted received signals in (1) and (2) were coincidences of the click of the lever and the clock-beat, so that not much error on this score should be found in the case of trained observers. Experiments, however, were made to determine this important point (Mr. Gill's 'Preliminary Account of the Determination of the Longitude of the Cape Observatory,' monthly notices, R.A.S., Vol. XLIII., No. 8), and the result was that the difference between any two of the observers, either in sending or receiving signals, or in a combination of the two, was less than 0·01 seconds. This personal equation may therefore be fairly neglected. The length of the cable from Lourenço Marques to Durban is 349·7 knots, resistance of copper conductor 11·35 ohms per knot, capacity ·283 microfarad per knot, and the capacity of the condensers is 38·54 microfarads. The length of the land line from the Observatory to Durban is 1,133 miles. Three relays were inserted, viz., at George, Fort Beaufort, and Umtata, so that to the resistance of the wire must be added the resistance of the instruments. The resistance of the whole line may be taken at a little more than nine ohms per mile. The following are the results of the observations:—

(1) Durban fast on Observatory—

| | H. | M. | S. | |
|---|---|---|---|---|
| Observatory sending ... | 0 | 50 | 12·29 | (2 coincidences) |
| Durban sending ..... | 0 | 50 | 11·92 | (2 coincidences) |

$$\therefore \text{ loss of time} = \frac{\text{M. } 0{\cdot}37}{2} = \text{S. } 0{\cdot}185.$$

(2) Lourenço Marques fast on Durban—

| | H. | M. | S. | |
|---|---|---|---|---|
| Durban sending ..... | 5 | 52 | 39·89 | (5 coincidences) |
| Lourenço Marques sending | 5 | 52 | 39·37 | (2 coincidences) |

$$\therefore \text{ loss of time} = \frac{\text{S. } 0{\cdot}52}{2} = \text{S. } 0{\cdot}260.$$

(3) Lourenço Marques fast on Observatory—

| | H. | M. | S. |
|---|---|---|---|
| Observatory sending ..... | 6 | 42 | 54·24 |
| Lourenço Marques sending ..... | 6 | 42 | 53·35 |

$$\therefore \text{ loss of time} = \frac{\text{S. } 0{\cdot}89}{2} = \text{S. } 0{\cdot}445.$$

The exact agreement of the loss in operation (3), which is independent of the observer at Durban with the sum of those in (1) and (2), shows that the personal equation of the observers in these signals was practically insensible, as I stated before. These results give for the cable a velocity of transmission of about 1,370 knots per second, and for the landline of about 7,630 miles per second (through three relays). There must, however, be some loss while the lever is moving from its position of rest to the lower stop. This distance was adjusted finely, and the antagonistic spring just sufficient to draw the lever back. I have no data at present to determine this time, but I do not think it would exceed 0·02 second. If this estimate be accepted, we should have for the loss of time on the cable before the current made itself sensible 0·24 second, which corresponds to a velocity of transmission of about 1,460 knots per second."

## ELECTRO-CHEMISTRY.—Inorganic.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 511.)

**Analysis of Copper Ores by Means of Electrolysis.**—As this series of articles is not of a technical character very few remarks are admissible on this subject. To carry out also processes of electrolytic analysis successfully, requires a knowledge of analytical chemistry, because the methods in nearly all cases (with other metals as well as with copper) are combinations of ordinary chemical and electro-chemical actions.

By electrolysis all the copper is separated from solutions containing free hydrochloric acid on the addition of ammonium or sodium chlorides, or sodium acetate. Similarly from solutions containing excess of ammonia, ammonium carbonate, or potassic cyanide. From a solution containing mercury, silver, bismuth, and copper, the last two metals are only deposited after the greater portion of the first two has separated. (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 283.)

The electrolytic determination of the amount of copper present in a liquid is more readily made than that of almost any other metal, and this agrees with the usually extreme degree of purity of the deposited substance. The last traces of copper may also be perfectly precipitated in a coherent state from a solution of blue vitriol containing two platinum electrodes, by a current of suitable strength. The deposited copper, however, is not perfectly pure if tartaric or citric acid is present. The electrolytic process is extensively used. Details of it may be found in Watts's "Dictionary of Chemistry," Vol. VII., pp. 384, 790; Vol. VIII., p. 559; *Chem. News*, Vol. XIX., 1869, p. 221, XXIV., pp. 100 and 172; XLI., pp. 25, 213; XLII., p. 331; XLIV., 1881, p. 279; XLV., 1882, p. 101, and XLVI., p. 105. *Jour. Chem. Soc.*, 1876, Part 2, p. 115; 1877, Part 1, p. 340; Vol. XXXVI., 1879, p. 276; Vol. XXXVIII., 1880, pp. 282 and 583; Vol. XL., 1881, p. 1,081; Vol. XLII., 1882, pp. 428, 660, 896, and 1,320.

**Separation of Nickel.**—Ni. Atomic weight = 59. A dyad cation. Less readily deposited than copper. From slightly acid solutions of salts of protoxide of nickel, magnesium deposits by simple immersion metallic nickel and hydrogen (Roussin, *Chem. News*, Vol. XIV., p. 27). Zinc amalgam deposits nickel from neutral solutions of nickel salts by simple immersion, and forms an amalgam (Damour, *Jour. Prac. Chem.*, XVII., p. 345).

By contact with a second metal, nickel is also in some cases deposited from its solutions. Stolba takes a boiling hot, one-third saturated solution of chloride of zinc, in a copper vessel, renders it clear by adding just sufficient hydrochloric acid, then adds a few particles of zinc, sufficient to cause a slight deposit of zinc upon the copper. He next adds either chloride or sulphate of nickel, until the mixture is distinctly green. The metals to be coated, viz., cast iron, wrought iron, steel, brass, or copper, are then immersed in the boiling solution in contact with zinc until they are coated (Watts's "Dictionary of Chemistry," Vol. VII., p. 850, also *Chem. News*, Vol. XXXV., p. 166). C. Méne coats either iron, steel, zinc, lead, copper, or brass with nickel, by immersing it in a boiling hot neutral solution of chloride of zinc, containing fragments of nickel. If the liquid is acid, the deposit appears dull (*Chem. News*, Vol. XXV., p. 214). A nickel-gold couple produces no deposit of nickel in acid or neutral, hot or cold, solutions of salts of nickel (Raoult, *Jour. Chem. Soc.*, Vol. XI., p. 646).

An aqueous solution of cream of tartar and hydrated nickel oxide, with a little soda, gave by the separate current process peroxide of nickel at the anode (Wernicke, Watts's "Dictionary of Chemistry," Vol. VII., p. 899).

**Electrolysis of Nitrate of Nickel.**—$Ni.2NO_3$. Molecular weight = 183. Nickel may be deposited by a separate current from a solution formed by dissolving one part of nitrate of nickel in one part of strong aqueous ammonia, and then adding 20 to 30 times its volume of aqueous bisulphite of sodium of specific gravity 1·199 (Roseleur). I have always found that when nickel solutions contained nitrates the deposited metal was of a bad colour.

In France a solution is prepared by dissolving four parts of nickel nitrate in four parts of aqueous ammonia and 150 parts of water holding in solution 50 parts of acid sodium sulphite. A very feeble current is used (Boden, Watts's "Dictionary of Chemistry," Vol. VIII., Part 2, p 1,388).

**Electrolysis of Fluoride of Nickel.**—By immersing crystals of silicon in an aqueous solution of nickel fluoride, containing free hydrofluoric acid, I observed that they did not become coated with metal; but by heating the crystals with ten times their weight of nickel fluoride to redness in a porcelain crucible, vivid incandescence occurred, and nickel was deposited and melted by the great heat evolved.

**Electrolysis of Chloride of Nickel.**—$Ni.Cl_2$. Molecular weight = 130. The simple immersion of copper in a solution of the double chloride of nickel and sodium is sufficient to deposit the nickel (Becquerel, "The Chemist," Vol. V., p. 408). Zinc throws down the metal from a solution of nickel chloride previously rendered alkaline by addition of ammonia.

One of the first really good liquids for depositing nickel by means of a separate current for practical purposes appears to have had its origin in the following experiments published by me:—"I have deposited nickel in the state of reguline white metal from a solution of the double chloride of nickel and ammonium, by making a lump of metallic nickel the anode in a strong aqueous solution of hydrochlorate of ammonium (sal ammoniac), and passing a strong current until the liquid acquired a pale greenish blue colour" (*Pharm. Jour.*, Vol. XV., No. 3, September 1, 1855, pp. 106 and 131). T. Fearn, in 1872, published the composition of a solution for depositing nickel, viz., 24 parts of sal ammoniac dissolved in 160 parts of water, and the liquid then saturated with protoxide of nickel at 120° F.

Martin and Dalamotte dissolve 1,250 grammes of citric acid, 500 of sal ammoniac (or ammonium sulphate), and 500 of nitrate of ammonium in 15 litres of water; heat the liquid to 80° C., and saturate it with recently precipitated hydrate of nickel, then add 2½ litres of aqueous ammonia; dilute to 25 litres, and after cooling add 500 grammes of ammonic carbonate, subside the mixture, and filter the liquid. Use the solution at 50° C. (Watts's "Dictionary of Chemistry," Vol. VIII., Part 2, p. 1,388).

**Electrolysis of Sulphate of Nickel.**—$Ni.SO_4$. Molecular weight = 155. Magnesium deposits nickel by simple immersion from a solution of nickel sulphate (Commaille, *Chem. News*, Vol. XIV., p. 188). Zinc throws down the metal perfectly from a solution of nickel sulphate rendered alkaline by addition of ammonia (A. Merry, *Jour. Chem. Soc.*, Vol. XIII., p. 311).

The best solution for electro-depositing nickel is made either by dissolving the crystallised double sulphate of nickel and ammonium, in the proportion of half a pound to a pound, in a gallon of water, or the double chloride of nickel and ammonium may be used instead. A large anode of nickel should be employed. Böttger states that the best solution for depositing nickel by means of a separate current is made by adding to crystals of proto-sulphate of nickel as much liquid ammonia as is necessary to dissolve them (*Pharm. Jour.*, Vol. III., 1843, p. 358). Nagel dissolves two parts by weight of crystals of sulphate of nickel in a mixture of six parts of aqueous ammonia of specific gravity ·909 and thirty parts of water, and uses the mixture at a temperature of about 100° F. Another liquid is composed of 100 parts of sulphate of nickel, 53 of tartaric acid, and 14 of hydrate of potassium, dissolved in a suitable proportion of water. It is said to yield a bright deposit of metal. Some recipes include nitrate of ammonium, or nitric acid, which is objectionable (*see* also A. C. and E. Becquerel, *Comptes Rendus*, Vol. LV., p. 18, also Kayser, *Jour. Chem. Soc.*, Vol, XXXIV., 1878, p. 537).

Another nickel solution is composed of 87·5 parts of nickel sulphate, 20 of ammonium sulphate, 17·5 of citric acid, and 2

Digitized by Google

litres of water (Hesse, Watts's "Dictionary of Chemistry," Vol. VIII., Part 2., pp. 1,118 and 1,388).

More recently nickel-sulphate-depositing solutions containing borax have been employed. I analysed one, and found it to contain sulphate and chloride of nickel, borax, and a small quantity of ammonia. A Mr. Powell, of Cincinnati, adds ½oz. to 1oz. of benzoic or pyrogallic acid to each gallon of the ordinary nickel plating solution "to improve it."

A solution of ferrocyanide of nickel dissolved in aqueous potassic cyanide has also been employed for depositing the metal.

In the deposition of nickel from the solution of the double sulphate of nickel and ammonium with a cast nickel anode the anode disintegrates to a loose powder upon its surface, and also by solution of the nickel a loose coating of impurity accumulates upon it, and falls to the bottom of the liquid, and collects as a yellow mud. The following are the results of a chemical analysis of the yellow substance :—

| | |
|---|---|
| Hydrated oxide of nickel | 52·7 |
| $SO_3$ (chiefly insoluble basic sulphates) | 11·5 |
| Moisture | 11·3 |
| Sesquioxide of iron | 9·4 |
| Sand (with particles of graphite) | 8·6 |
| Metallic nickel | 4·8 |
| Oxide of copper | ·7 |
| | 99·0 |

Also a trace of sulphur, but no silver, lead, or zinc, nor any metallic iron.

**Electrolysis of Selenate of Nickel.**—By adding to a solution of neutral selenate of nickel aqueous ammonia until the liquid was of a clear blue colour, and electrolysing with a nickel anode and a current from three Smee's cells, I obtained a brilliant and very white deposit of the metal.

**Electrolytic Analysis of Nickel Compounds.**—See *Chem. News*, Vol. XXIV., pp. 100 and 172 ; Vol. XXVI., p. 209 ; Vol. XXXVIII., p. 26 ; Vol. XLI., p. 25 ; Vol. XLII., pp. 75 and 331 ; Vol. XLVI., p. 105. *Jour. Chem. Soc.*, 1876, Part 2, p. 115 ; Vol. XI., p. 204, Part 1, 1877, p. 340, and Part 2, pp. 924 and 925 ; Vol. XXXIV., 1878, p. 537 ; Vol. XXXVIII., 1880, pp. 282, 583, 751, and 771 ; Vol. XL., 1881, p. 1,081 ; Vol. XLII., pp. 896, 1,320 ; Vol. XLVI., p. 105. Watts's "Dictionary of Chemistry," Vol. VII., pp. 791, 849.

**Separation of Cobalt.**—Co. Electro-chemical equivalent $\frac{59}{2} = 29{\cdot}5$. A dyad cation. Magnesium deposits metallic cobalt and hydrogen from slightly acid solutions of protoxide of cobalt (Roussin, *Chem. News*, Vol. XIV., p. 27). Thallium deposits a basic salt by simple immersion in a solution of nitrate of cobalt (W. C. Reid, *Chem. News*, Vol. XII., p. 242). Zinc amalgam deposits cobalt by simple immersion in neutral solutions of salts of cobalt, and forms an amalgam (Damour, *Jour. Prac. Chem.*, XVII., p. 345). Cobalt is not precipitated from its neutral solutions by means of zinc, except in the presence of a metal easily reducible by zinc, *e.g.* lead or copper, but not cadmium ; with copper salt present, if the liquid is acid, copper alone is deposited. A definite quantity of copper salt is necessary (Lecoq de Boisbaudran, *Jour. Chem. Soc.*, 1876, Part 2., p. 551). Cobalt is deposited upon steel or iron by contact of zinc in a boiling hot solution of zinc chloride containing a salt of cobalt (*Chem. News*, Vol. XXXV., p. 166). Mène deposits cobalt upon lead, iron, brass, or copper by immersing it in contact with zinc in a boiling hot and neutral solution of chloride of zinc containing fragments of cobalt (*Chem. News*, Vol. XXV., p. 214).

**Formation of Peroxide of Cobalt.**—An aqueous solution of cream of tartar and hydrated cobalt oxide, with a little soda dissolved in it, yields, with a separate current, a peroxide of cobalt, exhibiting magnificent colours upon the anode (W. Wernicke, Watts's "Dictionary of Chemistry," Vol. VII., p. 899).

By passing a separate current though a solution of oxide of cobalt in aqueous potassic cyanide, hydrogen and a small quantity of cobalt are deposited.

According to Troost and Hautefeuille, laminæ of electro-deposited cobalt sometimes contain as much as thirty-five times their volume of hydrogen (*Chem. News*, Vol. XXXI., p. 196).

**Electrolysis of Fluoride of Cobalt.**—$Co.F_2$. Molecular weight = 97. I electrolysed a solution of this salt in pure dilute hydrofluoric acid, by means of a current from a single Smee's cell, with an anode of cobalt, and a cathode of copper, but only a film of black powder appeared on the cathode in twelve hours.

(TO BE CONTINUED.)

## SOME OBSTACLES TO THE DEVELOPMENT OF ELECTRIC LIGHTING.

The future of electric lighting is a matter of great and growing importance. Both when viewed under its commercial aspects and when regarded in its relations to public convenience and health it claims attention by its magnitude. Whether or not electricity is destined to oust gas from the field altogether as a lighting agent is a question that must yet wait a long time for an answer ; but it is generally admitted that it will at least largely share the field with the older illuminant. The admission is in itself strong evidence of the secure ground occupied by the new light. At the time of its introduction its novelty precluded the possibility of forming an accurate judgment concerning its adaptability to the requirements of common use, and the consequent chances of its general adoption. But the knowledge since gained by experience has been sufficient to enable us to make a fairly just estimate of its qualities and its prospects, and the time has arrived when such an estimate is urgently called for. The wild visionary promises with which the new light was ushered in have naturally been unfulfilled, and the extravagant hopes which these promises raised have necessarily been disappointed. Confidence has in this way been grievously shaken, and undue distrust has taken the place of unfounded faith. The reaction which always follows a period of excitement, and which is strong in proportion as the excitement that preceded it was intense, has come, and its disastrous effects are making themselves painfully apparent. The balance, however, once adjusted, the matter will rest upon a more stable basis. To adjust this balance nothing can contribute more than a true appreciation of the present state of things.

The more conspicuous merits of the electric light are such as compel recognition at first sight, and they were consequently well calculated to raise alarm at the very outset among those whose interests were exposed to injury. The light which allows all colours, and delicate shades of colour, to be distinguished as in the perfect light of day was sure to make its advantages felt ; and the property which enables the light to exist without vitiating the atmosphere of our dwelling rooms could not fail to win favour. Hence it arose that defects, or what at the time appeared to be defects, were eagerly seized upon, and on such hastily assumed grounds predictions of speedy failure were made, and on all sides loudly proclaimed. It happened, too, so little was the subject understood, that these predictions were caught up and repeated by many electricians, by some even of eminence among them. Thus sanctioned by authority these assertions acquired weight, and in the public mind the attempts to render the new light practicable came to be regarded as hopeless. The points on which failure was foretold were numerous. It was maintained that the distance to which a lighting current of electricity could in practice be conveyed was limited to four or five hundred yards, and that, consequently, the "centres" would have to be so numerous that the scheme must become impracticable. Now, it is by no means certain that even under such conditions as were here assumed a scheme of lighting could not be economically carried out. A radius of five hundred yards from a "generating station" would include a very considerable area, and the magnitude of the works at each of such stations would be proportional to the extent and importance of the area of which it was the centre. But experience soon made it clear that such narrow limits were only imaginary, and that suitable currents could,

Digitized by Google

by a mere adjustment of electromotive force and resistance, be conveyed over much longer circuits without the ruinous loss of energy declared at first to be inevitable. Another obstacle to success, strongly insisted upon as being in the nature of things insuperable, was the great loss of available energy consequent on dividing the current among a number of lights. This objection was in everybody's mouth, and was urged on every occasion. It mattered not that the objectors were themselves profoundly ignorant of the science. Smatterers gave free scope to their dogmatic inclinations whenever the question of subdivision was raised; and men to whom magnetic fields were as little known as the Elysian talked glibly of the difficulties in the path of the electrician. The objection had, indeed, a substratum of fact to rest upon; the error lay in the narrowness of the view. When a certain current is forced through an incandescent lamp we obtain a certain intensity or quantity of light, and we do not get an equal total quantity of light when we divide the same current between two lamps. But we do get double the light when we force twice the current through the two lamps. Thus, by doubling the production of current we double the useful effect manifested as light. This being so, the only question was whether the requisite electric energy could be developed in the dynamo machine at a cost that would enable the light to compete on economical grounds with gas. The experience of the last twelve months has answered this question in the affirmative, and we now find some of the best companies and firms of good standing offering to take up large contracts at the price of gas. This is the best possible evidence not only that electric lighting does not necessarily exceed gas lighting in cost, but that it has already been brought to a practical stage of development. But, perhaps, none of the early predictions of failure have been so conspicuously falsified as that which was based on the cost of incandescent lighting *per se* and the difficulty of obtaining a "burner" of sufficient durability. It was unhesitatingly asserted by the great majority of electricians of every country that the only hope of success lay in the arc; that lighting by incandescence was by nature so wasteful of energy that no one with any claims to electrical knowledge would for a moment think of employing a system which stood thus self-condemned. Edison, by adopting this method of applying the electric current to the purpose of illumination, and by doggedly persisting in his pursuit of success in this direction after being repeatedly warned of its futility by the learned of Europe, provoked the jeers of the scientific world. Chemists, too, added their authority to that of the electricians, and declared the production of a carbon filament capable of withstanding the destructive effect of incandescence for longer than a hundred hours impossible. Yet we now see incandescent lighting not merely in high esteem, but likely to supersede arc lighting in all but a few specially favourable circumstances. And the best lamps in use have a life of not less than a thousand hours. This remarkable success has been achieved in a space of time that is astoundingly short; and few will grudge the rewards obtained by those whose unencouraged labours have brought it about. As one after another these seemingly insuperable obstacles were surmounted, the carping critics were compelled to fall back upon what appears to be their last position, namely, the impossibility of directly storing electric energy and the consequent risk of accidental extinction of the light. The numerous petty failures, incidental to every new undertaking, which marked the earlier attempts to establish the light on a practical basis gave force to this objection, and public confidence has been in some degree shaken on this point. But already storage by indirect means has been shown to be practicable, and the risks of a break-down have been reduced to a minimum by suitable arrangements of the mechanical details of a "station," and the provision of reserve machinery. A review of all these facts leads to the conclusion that, from a scientific and practical point of view, the present state of electric lighting is highly satisfactory and distinctly encouraging. The most sanguine hopes of its originators have been fully realised, the experimental stage has been successfully passed through, and, though no doubt further improvements are yet required to render the system capable of coping with all the conditions and circumstances to which it will be subjected in practice, enough has been done to warrant its adoption on a large scale. The fact that this point has been reached in the short space of time covered by three or four years justifies the belief that what still remains to be done will be speedily accomplished.

When we turn from the scientific and practical to the purely commercial point of view, we find the existing state of things to be extremely unsatisfactory and bitterly disappointing. In both cases events have belied public expectation. In the former the prognostications portended certain and speedy failure; the course of events has brought rapid and complete success. In the latter the predictions promised immediate and large demands upon the supply companies hastily launched to meet the want as soon as scientific success appeared probable, with profits of corresponding magnitude; the present state of things shows an almost total absence of business, with its consequent uncheering balance-sheets. Companies that were started under favourable auspices have lapsed into a state of baneful inertia for want of opportunity for employing their capital; while others, unsound from the beginning, have either passed out of existence or are in a moribund condition. Signs of vigorous life are nowhere apparent. Some companies are occupied with a fair amount of business in small installations. These may, however, be counted on the fingers of one hand. But this is not the kind of work expected, nor is it that which will long provide sustenance. The application of the light on a large scale has been the object kept in view by these corporations, and only such extensive adoption of the system could afford them remunerative and lasting occupation. The orders for these large installations are, however, not forthcoming; and, strange as it may at first sight appear, they are not very eagerly sought after. This latter fact may be due to a dawning consciousness on the part of the existing lighting companies of occupying a false position.

These unexpected results demand an inquiry into the causes which have led up to them, and into the apparently anomalous state at which the matters in question have arrived. For it is surely no common thing to find the commercial prospects of a new industry becoming gloomy just when the technical difficulties that hindered its development have been overcome and the soundness of its character practically demonstrated. Such an inquiry will reveal the somewhat startling fact that the present dead-lock is a necessary and natural consequence of the successful issue in which the efforts of scientific men and practical engineers have terminated. By overcoming the difficulties which beset it at the outset they have brought the system of electric lighting within the range of everyday requirements. It has been shown free from the defects at first attributed to it, and proved to be susceptible of general application as a substitute for gas. The opposition which gathered round it at its beginning has been largely overcome, and the prejudice which arises against every new thing has ceased to make itself felt as a serious obstacle to its progress. The time has therefore arrived for its general adoption. And not only is the application of the system on an extensive scale demanded by public requirements, but it is obviously necessary that such an application should be made to render the undertaking profitable. Gas being already in possession of the field, the electric light has to compete with it on its own terms. The cost of gas, which may not be greatly exceeded in the case of electricity, is estimated, not according to that which would be incurred in experimental works, but according to that which is the outcome of very extensive application and years of experience. The relative cost of the two systems can be learned only by establishing them under the same conditions.

The supply of artificial light is a matter differing greatly in character, and still more widely in point of magnitude from the erection, maintenance, and working of telegraph lines and telephonic means of communication. The application of systems of this nature is restricted within relatively narrow limits. Even when developed to the greatest conceivable extent these can never equal, in the universality of their requirements, the means of light supply. They may, therefore, be effectively dealt with by a few joint stock companies working over a very extensive area. But in lighting we encounter quite other

Digitized by Google

conditions. The demand for artificial light is universal; it is needed in every dwelling house. Would it ever have been thought possible for half-a-dozen companies, even with numerous affiliated offshoots, to supply the whole of this country with gas? A very little consideration of the subject will suffice to reveal what is involved in lighting a town by electricity. It means the establishing of central "generating stations," provided with sufficient engine and machine power to produce electricity adequate to the needs of the whole area to be lighted, with a considerable proportion of that power in reserve for security against accidents. It means the laying down of an intricate and costly network of copper circuits over all that area, and in communication with the central stations. It means, further, the addition of branch circuits from the mains to each house; nay, more, to every room, hall, and passage in every house in every district. It means, again, the introduction of a more or less large number of lamps into each of these numerous subsidiary circuits. And, finally, it means the maintenance of this extensive and complex system in constant, efficient, and certain action. Those who are conversant with the cost of work of this nature will not long reflect upon these facts without becoming aware that to carry out such an undertaking in only one town of moderate size would require all, and in the case of some, more than all the available capital of any one of the existing lighting companies. It is probably the recognition of this fact that makes the companies shrink from involving themselves in undertakings of such magnitude. Conscious of their inability to cope with the task they have inconsiderately set themselves, they are in no haste to have it imposed upon them. Hence arises their seeming want of enterprise and the apprehension with which they regard the future.

But were the conditions other than they are, and, in this respect, altogether favourable, the reluctance of the local authorities to deal with outside companies would probably have been alone sufficient to bring about the dead-lock to which we have come. By "local authorities" it is not meant to denote merely the governing boards, but all men of capital and influence resident within the district by whom local enterprise is set on foot, and of whom the nominal authorities are only the official representatives. The true causes of this reluctance are not far to seek. For some unaccountable reason, however, they are not put forward in discussing the subject, but some other objections, which really have but little weight with those who raise them, are insisted upon as determining the question. In some degree, no doubt, the remarkably rapid development of the system has produced a feeling of uncertainty and insecurity. Within the short period of a few months we have seen inventions spring up, flourish, and disappear to make room for better; and it is naturally felt that further improvements may, in a short time, lead to the abandonment of what are now the most perfect forms and devices. A want of confidence is also induced by suspicions of weakness in the financial state of some of the existing lighting companies. Not all of these were set afloat on a sound commercial basis, and the difficulty of discriminating suggests the prudent course of waiting the test of time. A more weighty influence is that which is brought to bear by those who are directly interested in the production of gas, always a strong section in provincial towns. The opposition encountered by electricity in this direction is persistent and determined, and it is formidable in proportion to the magnitude of the interests at stake. This opposition would not, however, alone arrest or even seriously retard the progress of electric lighting. Its manifestly selfish character deprives it of much of its force. But the chief cause of the reluctance evinced by the local authorities to introduce the electric light within the limits of their districts is to be found in their unwillingness to yield up what is likely to be a fruitful source of profit to persons who do not belong to their own community, and who will intervene in their affairs only to withdraw capital. The intervention is resented as an unwelcome intrusion. It is a matter which touches the interests of all, and, consequently, there exists a unanimity of feeling that renders the opposition arising from it irresistible. The manufacture of gas forms at the present time one of the staple industries of every town, and it affords a suitable means for the investment of small savings, easily accessible to all, and combining large profits with safety. As a consequence, the shares are distributed among all classes, and they are all held in the town. To admit an outside company to light by electricity is to deal a ruinous blow at an important home industry, in which a large proportion of the inhabitants are directly interested, for the benefit of a body of speculators who have no part or lot in the local affairs. The question asked is—If our property in gas is to be destroyed or seriously depreciated, why may we not provide compensation by establishing for ourselves a property in electricity? Why may we not do for the electric light what we have done for gas? That is, form our own electric lighting companies and work them for our own profit. If a clear way of doing this were seen, the ever active spirit of competition would speedily set the enterprise on foot. But at present it cannot be done without incurring the risk of becoming entangled in the web of patent rights held by existing companies. The way not being clear, the authorities hold back, awaiting a more favourable opportunity, which they know well must soon come. Hence, the further progress of electric lighting is stayed until matters can be set upon a different footing.

The remedy for this evil becomes apparent as soon as the causes which have led up to it are clearly perceived. The companies now in existence, being unequal to the task of supplying light on an extensive scale, must, to find profitable employment of their capital, limit their business to the manufacture of the requisite apparatus, and the work of supplying any given district with light must be undertaken by a local company formed for that purpose from among the inhabitants of that district. To put the matter in another way, electric lighting must be carried out on the same basis and in the same manner as gas lighting. With the example of gas lighting before us, it is strange that any other system of application should have been thought practicable. The matters to be dealt with and the conditions to be encountered in dealing with them being similar both in character and extent, the use of the same means seems to suggest itself. It needed, indeed, but little shrewdness to perceive that only such means could be adequate to the purpose. The necessity for dealing with electric as with gas lighting by local independent companies has now, however, made itself felt, and only the opportunity is wanting for effect to be given to the conviction. The opportunity is to be afforded by the present companies renouncing their claim to be the sole purveyors of light, and evincing their willingness and ability to furnish the requisite apparatus to whomsoever is desirous of becoming their customers. When the naturally distinct branches of manufacture and supply shall have been separated, the new industry will have been fairly started on the road to commercial success. That a profitable business is to be found in the manufacture of the apparatus of electric lighting is beyond doubt, and it is scarcely less certain that satisfactory dividends are to be earned by a properly-managed supply. A sound company, formed solely for the supply of light, untrammelled with patent rights, and possessing the goodwill of its customers can, provided only it set about its work with the caution needful in every new enterprise, hardly fail to achieve success. In such a case the obstructionist opposition now raised on all sides whenever an attempt is made to introduce the new light on a large scale would not be offered. Placed upon such a footing, the progress of electric lighting may be expected to be rapid and sure, since, not only will the obstacles have been removed, but an incentive of another and an irresistible nature will have been given to the consuming public to adopt the superior illuminant. Even if the cost were slightly greater than that of of gas lighting, the fact would not count for much when the consumer was directly interested in the dividends of the supplying company. Eventually this state of things must be arrived at; but whether it shall be sooner or later will depend, in a great measure, upon the line of action followed by the companies who now have the matter in their own hands.

A gigantic task like that of town lighting is not only utterly beyond the power of the original companies, but it is altogether beside their functions. The work of a pioneer com-

PRESE LIBRARY OF THE UNIVERSITY OF CALIFORNIA.
Digitized by Google

pany in a case like this is to demonstrate the practicability of the system and its adaptability to common use, and to show that it can compete advantageously with gas on the grounds of convenience and cost. But beyond this it cannot go by reason of the magnitude of the thing. To attempt anything more would be to court disaster. It must be admitted that this function has been satisfactorily performed by the original companies, at least up to a certain point. It remains for them to show an installation on a large scale; to light at least one extensive area; and to demonstrate that on such a scale the cost of the electric light can be made to compare favourably with that of gas. But having done this they will have fulfilled their purpose, and as they will no longer occupy a useful position, they cannot continue profitable. Thus they will be compelled by the force of circumstances to make way for other more suitable agencies. To this stage they will have naturally and inevitably come. It is of the nature of every new system in course of development to outgrow the sufficiencies of the moment. A mechanical device is superseded by another of greater efficiency or of less cost, or a total change of the principles on which an apparatus is constructed leads to the complete abandonment of pre-existing forms and combinations. The progress of discovery has already rendered obsolete many of the earlier forms of lamps, and has materially modified all that have survived. For like reasons, the commercial conditions under which a new system is launched may become in a little time inadequate to the requirements of altered and more extended relations. Obsolete mechanical contrivances are easily and quickly thrown aside, but commercial institutions, when they have served their purpose and cease to be adequate to the growing exigencies of the times, are much less willingly relinquished. In the one case, the sacrifice to be made is but trifling; in the other, the consequences are disastrous to important individual interests. Large amounts of capital being at stake, the change is deferred till the latest possible moment. The two cases are strictly analogous, however. The lumber of abandoned mechanical devices which encumbers the workshops of the inventor—abandoned not because they failed to effect the purpose for which they were designed, but because a need for them no longer exists—finds its true counterpart in the lumber of unprofitable financial associations and decaying joint-stock companies, whose use has passed away in the further development of the thing which called them into existence. The disappearance of these companies from the field, whether by their conversion into mere manufacturing corporations, or by the inevitable dissolution which otherwise awaits them, will remove the most serious obstacle that now obstructs the further development of electric lighting, and set free commercial enterprise hitherto held in check.

## ON MECHANICAL DYNAMOMETERS.

BY GISBERT KAPP.

(CONTINUED FROM PAGE 346.)

All the transmission dynamometers which were described in the foregoing articles depend upon the use of springs, and contain, therefore, an element of uncertainty by reason of a possible variation in the elastic power of the springs. Frequent recalibration becomes thus necessary, and constitutes a drawback, which has led inventors to search for a more positive and unchangeable force wherewith to measure the power transmitted. Their choice naturally fell upon gravity, and hence we find a number of dead weight dynamometers suggested or in actual use. One of the earliest forms is that designed by S. Brown, of Lowell, and illustrated in Appleton's "Dictionary of Mechanics" (1852). It consisted of three spur wheels geared together, as shown in Fig. 22, where the middle wheel B transmits the power from wheel A, which is driven by the prime mover to wheel C, which gives the power off to the machine under test. If the wheels revolve in the direction of the arrows the bearings of the wheel B must resist a downward pressure, which is about equal to double the pressure between the teeth, that is, to double the circumferential power transmitted. We say about equal, because the friction between the teeth and in the bearings, and the varying radius of contact, which is unavoidable with externally-geared spur wheels, introduce certain errors and destroy the absolute equality which would exist if the machine were theoretically and practically perfect. The bearings of the middle wheel are mounted in a sling, which hangs from a lever, one end of which can be weighted to resist the downward pull of this wheel, whilst the other end is provided with a dashpot to take up shocks and jerks which are more or less

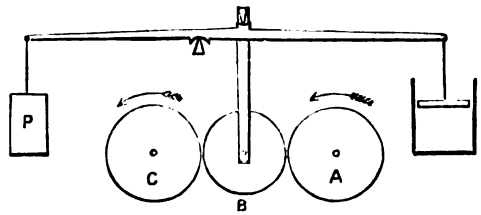

FIG. 22.—Brown's Dynamometer.

inseparable from the transmission of power by gearing. Let $d$ be the diameter of wheel C on the pitch line in feet, $n$ its number of revolutions per minute, and P the pull on the sling in lbs.; the horse-power transmitted is then

$$\text{H.P.} = \frac{P \pi d n}{66{,}000}.$$

This dynamometer has, however, some weak points which will be obvious to the reader. In the first place, the force necessary to balance the strain transmitted is double the amount of the strain, thus necessitating the working parts to be very heavy, then friction in the journal and between the teeth is registered as if it were work transmitted, and, lastly, a slight vertical displacement of the middle wheel not only causes the wheels to gear badly, but by altering the radius of contact between the teeth makes the above formula incorrect.

The latter defect has been completely remedied in White's transmission dynamometer (sometimes called the American dynamometer), which is shown in Fig. 23 in plan and eleva-

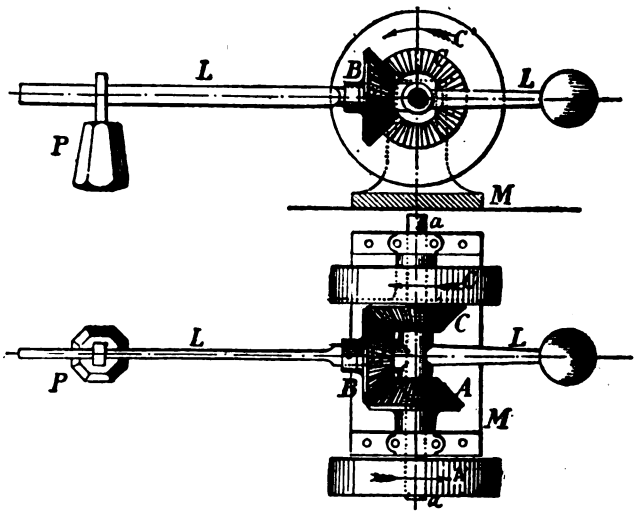

FIG. 23.—White's Transmission Dynamometer.

tion. This machine is practically nothing else but Brown's spur wheels translated into bevel gearing. The power is received on pulley A, which is keyed to the shaft $a\,a$. To the same shaft is also keyed the bevel wheel A, gearing with an equal wheel, B, and thus transmitting the power to C, which is fast with pulley C', both, however, being loose on the shaft $a\,a$. The middle wheel is mounted on a spindle, which, by means of a sleeve, also loose on the shaft, can move round it through a certain angle, all the wheels remaining properly in gear whatever the position of B. The spindle of this wheel is prolonged into a lever, L, which has to be weighted in order

Digitized by Google

to counterbalance the tendency of the wheel B to be carried upwards, if the movement of the pulleys takes place in the direction shown by the arrows. The lever is prolonged beyond the sleeve and provided with a balance weight.

Let R be the distance in feet of the weight P in pounds, and $n$ the number of revolutions per minute of the wheel C, then the horse-power transmitted is

$$\text{H.P.} = \frac{P \pi R n}{33{,}000}.$$

It will be seen that the size of the bevel wheels does not enter into the formula, but only the distance of the weight from the centre of the shaft. This is analogous to the formula for the Prony brake, where it is the radius of the weight and not the size of the pulley which enters into the calculation. With the exception of the advantage of keeping the wheels always in perfect gear, White's dynamometer has the same faults as that last described, any friction in the journal of B, in the sleeve, or between the teeth being registered as if it were work transmitted.

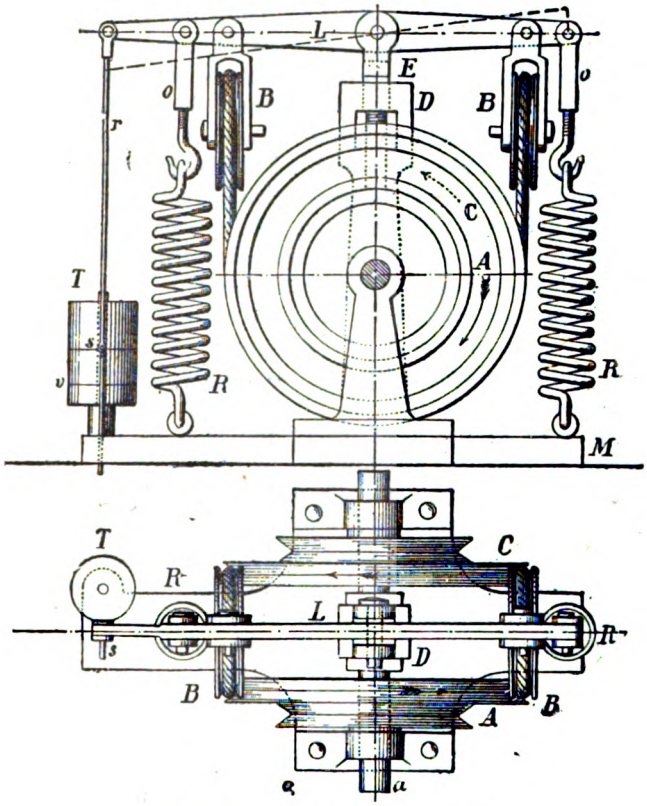

Fig. 24.—Raffard's Dynamometer.

In the year 1875 Mons. N. T. Raffard invented a dynamometer, which is in principle very similar to White's. It is shown in Fig. 24 in plan and elevation. The description as given by M. Raffard in the *Bulletin Mensuel*, No. 208, will best explain it :—

"This apparatus is founded on that of White, the only difference being that the bevel gear is replaced by rope gearing, so as to avoid the noise occasioned at high speeds. Instead of the intermediate wheel two rope pulleys are used, which are fastened by hinge slings to the lever L. As in White's dynamometer the force acting on the lever is double that transmitted. Instead of a weight two opposing springs are used, the tension of which can be regulated by screws. A small drum, T, turning with the wheels, serves to receive a paper, upon which a pencil, *s*, marks a diagram of the strain transmitted."

An important advantage which this dynamometer has over White's is that its friction and consequent error can be considerably reduced without unduly increasing the weight of the whole apparatus. The rope wheels should be of large diameter, of strong and light design, and the rope very flexible.

But although in this manner journal friction in the two rope pulleys can be minimised to any reasonable extent, it cannot altogether be avoided, and it was to eliminate entirely this source of error that Raffard invented his ingenious internally-geared dynamometer, shown in Fig. 25 in elevation and in Fig. 26 in plan.

The wheel A, supported in fixed bearings, receives the power from the prime mover by means of a universal coupling, and transmits it through wheel B on to the internally-geared wheel C, the outer rim of which forms a pulley from which a belt is led to the machine under test, or that machine may be driven direct from the universal coupling C'. The bearings of B are not fixed to the frame, but mounted on a lever D, which is supported on a knife edge, as shown, the other end being connected to another lever, T, which can be weighted to counterbalance the downward pressure which the bearings of B experience if the movement takes place as shown by the arrows.

Fig. 25.—Elevation of Raffard's Internally-geared Dynamometer.

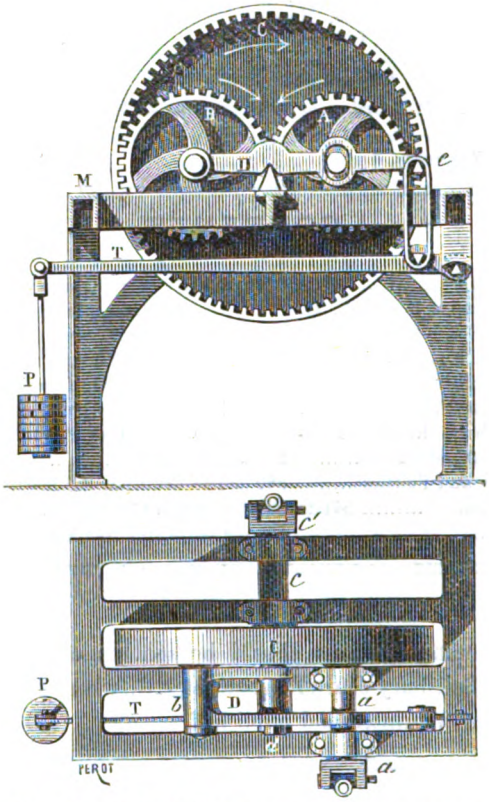

Fig. 26.—Plan of Raffard's Internally-geared Dynamometer.

The fulcrum of lever D is arranged to stand exactly midway between the centres of the two equal wheels A and B, and coincides, therefore, with the point of contact of the two pitch lines. In consequence of this arrangement the pressure between the teeth of A and B is taken up directly by the fulcrum without producing any tilting of the lever; the latter is only influenced by the pressure between the teeth of B and C, which acting at a distance $2r$ (where $r$ is the radius of pitch-line of B) produces at a distance $r$, that is in the bearings of B, a downward pressure equal to twice the force transmitted.

In this respect the internally-geared dynamometer is similar to those already described, but it has the great advantage that the friction between the teeth of A and B and the friction of the bearings of B are not registered, as is the case in the other instruments.

The fulcrum of the lever D being very nearly in the centre of wheel C, the centre of B remains nearly equidistant from the centre of C for all positions of the lever, consequently the two wheels remain always perfectly in gear.

(TO BE CONTINUED).

## TELEGRAPHY AND POLITICS.

Prince Bismarck's threatened retirement, or partial withdrawal, from the conduct of Prussian affairs has afforded him an opportunity of uttering a few more of those disagreeable truths for which he has long been famous. Life is getting too short for him to be "unctuous," he says, meaning that he cannot spare time any longer to be decorously insincere or studiously civil; and among the things which have already shortened his valuable life he explicitly mentions the telegraph. We cannot remember a time when the illustrious Chancellor of the German Empire was ever unctuous about anything, and if he has spared the telegraph hitherto, we should have thought it was because he had no time to anathematise it. As to its having shortened his days, we are reminded of that celebrated general, himself as irascible as the German Chancellor, who exclaimed of one of his over-slack followers: "Confound the fellow, does he want to live for ever?" Prince Bismarck must be somewhat greedy if, at his time of life and with nothing more seriously amiss with him than neuralgia, he complains that a career of unprecedented labour, responsibility, and duration has been prematurely shortened. But it is no doubt the fact that the particular thing complained of in this instance has greatly added to the labours and responsibilities of office, and although it has not, to all appearance, impaired his faculties, it has probably shortened Prince Bismarck's temper, and rendered his position in the Prussian Parliament as burdensome to himself as it is exasperating to his enemies. He will still be virtual head of the German Empire, and the telegraph will torment him as unceasingly as ever; but in his retirement he can blaze away without the least restraint, escaping the inevitable friction which public life entails, and which, except to people who are profoundly satisfied with themselves, is more exhausting than mental or bodily toil.

It is undoubtedly true that the invention of the telegraph has immensely increased the cares and burdens of men in the position of Prince Bismarck. I have, he says, ever to be on the alert for events which may directly or indirectly affect the interests of my country; and the occurrence of those events is flashed to us daily and almost hourly, no matter how remote the place from which the intelligence has to come. There is no repose, for not only is the world for ever moving, but the telegraph brings us word of its every movement. Nations can no longer mind their own business, unless they are content to be effaced and have no business of their own to mind; one nation's business is every nation's business nowadays, the telegraph having united them in a bond of universal publicity and consequently of universal dependence. At no great distance of time perhaps this bond may result in mutual trustfulness and amity. When to steal a march on one's neighbour becomes utterly impossible the chances are in favour of our agreeing to live with him in peace. But this millennial period has not yet arrived, or at all events its arrival is not yet generally appreciated; consequently men at the head of affairs have to maintain an attitude of constant watchfulness and mistrust—an attitude trying to the nerves of even such men of iron as Prince Bismarck. The element of time which formerly set a wide interval between political action and its publication often contributed to its being passed over in silence. Something of that kind may be seen going on in the remote districts of Central Asia, from which news still reaches Europe with almost old-fashioned slowness. On the other hand, in the more accessible regions no shot can be fired without its echo reaching every Cabinet of Europe, and its possible consequences being the subject of anxious consideration. It is true that on some shoulders this burden of the telegraph wires sits very lightly indeed. Nobody can discover that the existence of the Eastern Telegraph Company, for example, makes the slightest difference to the present English Ministry. To all appearance they are as placid under the flood of telegrams from Cairo as under the drought in the region of Khartoum. Like Prince Bismarck, perhaps, they wish that all telegraphs were in that condition which mercifully leaves us in ignorance of what is going on above Shendy; but unlike him, they "wait for despatches," and treat all submarine cables as if they were non-existent. This is the old-fashioned manner; but it is not given to every statesman to be old-fashioned; most Continental statesmen prefer to be thought vigilant and patriotic. Prince Bismarck is content to plead merely that he is old; and although it may be doubted whether the cares imposed by the telegraph shorten life, they certainly tend to crowd into it a great deal more than it was wont to carry, and much more than can be borne with unruffled temper.

In another sphere of political activity the telegraph is proving itself equally vexatious to individuals, and even more

Digitized by Google

conspicuously serviceable to the community. In this case, however, we refer to commercial affairs, which are included in the political only in its broadest signification. Within the last twelve or fifteen years trade has been revolutionised by international telegraphy through submarine cables. At first it seemed to lend itself to the formation of trade rings and conspiracies for the manipulation of food supplies; but the means employed for checking and controlling the market soon became instruments of publicity, rendering all such private combinations futile. To hold back supplies in one distant market is of no avail when your customers can wire to another market for what they want, and the task of creating a fictitious scarcity is gradually being rendered impossible by the universal dissemination of information relating to the world's markets. As was recently observed by a contemporary, the laying down of telegraph cables all over the world has also tended permanently to lower the prices of commodities. Formerly a merchant had to wait payment until delivery of his merchandise, the price it would fetch remaining an uncertainty until the cargo was sold. Now he can sell by telegraph before shipment, and can receive his payment at once by the same medium. The risks being thus diminished consumers are certain to reap the benefit. In commerce, therefore, the beneficent operations of the telegraph have been swift and obvious. What the princes of commerce say about it we have yet to learn. If making a fortune is as exhausting as creating an empire, at all events we do not hear any complaints from the fortune makers. Those who lose fortunes may attribute their disaster to the telegraph, just as Prince Bismarck credits it with his loss of health; but so long as nations profit in trade and political security these personal complaints will pass unheeded.

## CORRESPONDENCE.

### "THE HEATING EFFECTS OF ELECTRIC CURRENTS."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with interest the paper of Mr. W. H. Preece on "the Heating Effects of Electric Currents," given to the Royal Society on April 3rd, and reproduced in *The Electrician* of this week. I have myself been engaged with experiments on this subject since the 9th November last, and hope soon to be able to publish my results. Meantime may I ask for space for a few remarks on Mr. Preece's paper, as his results are, so far as I can see at present, considerably at variance with those which I have obtained?

My experiments were undertaken, at the desire of Sir William Thomson, for the purpose of obtaining definite information on this subject, so fraught with importance in relation to the great problem of electric lighting. A special object was to obtain data as to the effect of an ordinary insulating coating in keeping wires warm or the reverse. On March 3rd Sir William Thomson gave a paper to the Royal Society of Edinburgh on "The Efficiency of Clothing," in which he showed, from theoretical considerations, that a spherical body, or a cylindrical body, will be kept cooler, instead of warmer, by a covering if the radius of the sphere or cylinder be less than $\frac{k}{2e}$ in the one case, or than $\frac{k}{e}$ in the other, where $k$ is the thermal conductivity, and $e$ the emissivity of the coating. He exhibited in experimental verification of the theory a number of wires on which I had experimented, all of them the same No. 22 copper wire, one of them bare and brightly polished, the second bare but unpolished, and others coated with (1) shellac, (2) paper and shellac three coats, (3) and (4) cotton wool of different but very considerable thicknesses tied on with thread, (5) paper rolled lightly many times round the wire. In testing these wires a powerful current of electricity was kept up through each till the temperature became constant, and it was found that the bare polished wire was the hottest, while the covered wires were all more or less cooled by their coverings. On this subject I have already obtained a considerable number of results, and I am still experimenting on it.

I have also experimented on uncovered copper wires of various diameters exposed to the air and in vacuum, and it is here that I have met with results seemingly different from those of Mr. Preece. The theory of Mr. Preece's experiment is not given completely in his paper. It will aid in what I have to say if I put down here the expressions for the heat developed in and the heat lost from a uniform uncovered wire of any material when a current of electricity is passing through it and maintaining a permanent temperature.

Let C be the current in absolute measure, R the resistance of the wire per unit length, and let J be Joule's equivalent also in C.G.S. units; then if H be the quantity of heat developed per second in thermal units C.G.S. (*i.e.*, the quantity of heat required to raise one gramme of pure water from 0°C. to 1°C.),

$$H = \frac{C^2 R}{J} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

But if $\sigma_t$ be the specific resistance of the wire at temperature $t$°C. and $d$ the diameter of the wire,

$$R = \frac{4\sigma_t}{\pi d^2}.$$

Hence

$$H = \frac{C^2}{J} \times \frac{4\sigma_t}{\pi d^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Now, let $e$ be the emissivity of the surface, that is the quantity of heat lost per second per square centimetre of surface per degree of difference between the temperature of the radiating body and that of the surroundings. Let $t$ be the temperature of the wire and $\theta$ that of the surroundings, then the heat lost per unit of time and per unit of length of the wire will be given by

$$H' = \pi d e (t - \theta). \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

If the heat lost equals that supplied by the current, that is, if the temperature of the wire heated by the current and losing heat by radiation remains constant, we shall have

$$H = H';$$

or

$$\frac{C^2}{J} \cdot \frac{4\sigma_t}{\pi d^2} = \pi d e (t - \theta);$$

whence

$$C = \mu e^{\frac{1}{2}} d^{\frac{3}{2}}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

where

$$\mu = \sqrt{\frac{\pi^2 J (t - \theta)}{4\sigma_t}}. \quad . \quad . \quad . \quad . \quad (5).$$

Suppose, now, as in Mr. Preece's experiment, that $t$ is chosen (viz., dull red heat) and $\theta$ remains unchanged, which will be nearly true, as the temperature $t$ is so very far above that of the walls of his dark chamber; we shall also have $\sigma_t$ fixed. J is constant ($42 \times 10^6$), and $\pi^2$ is 9·866. Hence $\mu$ of formulas (4) and (5) is constant for wires of different diameters, but of the same substance, heated to the same temperature.

Mr. Preece, virtually assuming that $e$ is independent of the size of the wire, which is doubtless the case for large surfaces, has used the formula

$$C \propto d^{\frac{3}{2}}$$

which seems to have been found in agreement with his experiments. I commenced my experiments last November with this formula as the foundation of my preliminary estimate of the amounts of thermal effect to be expected; but to my surprise I have found it very far from being verified. I find that with small wires there is a great deal more loss of heat under similar circumstances than with large wires, that is, that the value of $e$, if (4) be taken as a pilot formula, is much larger with small wires than with wires of large diameter.

Digitized by Google

The emissivity of polished copper surface and surface coated with lampblack has been determined with accuracy by Mr. D. Macfarlane, *Proceedings* Royal Society, 1872, p. 93, in absolute measure for a copper globe of 4 centims. in diameter, and found to be about $\frac{1}{4000}$th of the thermal unit C.G.S. per square centimetre per second per degree of difference of temperature for the polished surface with a little over 60° C. of excess of temperature, and for the blackened surface with excess of 5° or under. For round wires of small diameter I have found very much larger emissivity than Macfarlane's $\frac{1}{4000}$th, and, as said above, greater emissivity the smaller the wire. I have obtained different values of $e$ for wires of different sizes, and for a small wire a numeric as high as about $\frac{1}{650}$th at a temperature of about 70°C.

I do not know that this is to be wondered at, though it certainly was unexpected when we consider the matter in connection with some of the experiments of Aitken on the now celebrated "dark plane," showing the disturbance produced in the air in the neighbourhood of a heated wire. The result of the whole is that a small wire will lose heat much more rapidly than a large wire under similar circumstances; and I should expect that it would require currents greater for small wires and smaller for large wires than corresponds to proportionality to $d\sqrt{d}$ to maintain the same temperature in them.—Yours, &c., J. T. BOTTOMLEY.

The University, Glasgow, April 14, 1884.

P.S.—To avoid misconception, I wish to remark that up to the present time I have only experimented at temperatures very much lower than those used by Mr. Preece. I have not yet gone higher than 80° or 85° Centigrade. It is to be noticed that at very high temperatures, such as dull red heat or the fusion temperature of platinum, the separate effects of radiation and of convection, which are included in the theories of Newton and of Fourier under what has been called *emissivity* in my letter, may hold relations to each other and to the whole phenomenon very different from those which they hold at low temperatures. Thus it is quite possible that at very high temperatures, where radiation becomes predominant, the emissivity for small and for large wires may approximate to be the same. This would correspond to what Mr. Preece has found, though of course the subject will require investigation.

From what has been said it is also obvious that, so far as concerns wires to be used as leads in electric lighting, we must be cautious about applying results obtained at very high tempe ratures to cases where the temperature must essentially be kept comparatively low. J. T. B.

## THE ELECTRIC LIGHT IN FOREIGN RAILWAY STATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having recently passed through some of the most important stations both in France and Italy I have had an opportunity of comparing their standard of lighting with that employed on my last visit two years ago. To begin with the Gare St. Lazare, Paris. There is a retrograde movement which has taken the successive stages of Serrin lamps, Phare gas burners, incandescent lamps, and finally ordinary gas burners of a very inferior description. At the Gare du Lyon, Paris, the De Mersanne arc lamp seems to hold its own, though the other important stations are still lighted with Phare gas burners, with the exception of Marseilles, where the De Mersanne system is used both inside and outside the station, and I must say answers fairly well. To see station lighting *par excellence* one must travel in Italy, and note the well arranged installations at Turin, Pisa, Rome, and Naples, in each of which alternating current lamps are placed at frequent intervals, and so arranged that only all those in the immediate proximity to the train are lighted, thus reducing the high standard of lighting when it is not required. At Pisa every description of gas burner has been tried, not omitting the Siemens, which after a year's experience has been relegated to the scrap heap. The example of the Alta Italia Railway might, I think, be followed with advantage by our English companies.

The installation at Rome comprises about eighteen arc lamps suspended inside, and the same number on standards outside for the marshalling of the trains. These are on the Lampe Soleil system, and give a well-distributed light, but for economy I should prefer more powerful lights on higher poles.

As regards street lighting gas is predominant everywhere, both in France and Italy. There is, however, a considerable demand for incandescent lights, both in houses and factories. In the Riviera especially, where there are a large number of detached villas, a good field is open to a company willing to furnish electricity; and as the price of gas where obtainable is never less than 30 centimes the cubic metre—say 580 of the 1,000 cubic feet—a profitable business could be formed, especially if the natural water power was utilised.

With apologies for the length of this letter.—Yours, &c.,

KILLINGWORTH HEDGES.

Naples, April 10th.

## THE ELECTRIC LIGHT FOR RAILWAY TRAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: So many friends have spoken to me about the report of my reply at the Society of Telegraph Engineers on the 27th ult., given in your journal of the 5th inst., that I beg you will allow me to point out that in one place I am made to say the very opposite of what I intended.

With me the question of cost is always the first consideration, for I believe that no light, no matter how good or how reliable it may prove, will ever be adopted on railways unless it is cheap also; and what I said was that it seemed to me of far more importance to decide whether or not a good and cheap light could be produced in the way I had suggested than to discuss the amount of inconvenience which passengers might be expected to suffer from having their lamps put out for a few minutes at stations which should be so well lighted as to render the carriage lights quite unnecessary.—Yours, &c.,

WM. H. MASSEY.

6, Westminster-chambers, S.W.,
April 16, 1884.

## THE CAUSES OF HEATING IN THE IRON CORES OF ARMATURES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 29th ult. Mr. Nalder refers to the experiment of Dr. Joule, proving that when iron is magnetised an increase of $\frac{1}{20000}$ takes place in its length, and draws my attention to this fact, as supporting the opinions recently expressed, that the heating of the iron cores of the armatures of dynamo machines is a result of molecular action rather than of the generation of eddy currents.

I was acquainted with this experiment at the time the discussion to which Mr. Nalder refers took place, but do not consider that this molecular action can be held responsible for more than an exceedingly feeble heating effect. The subject is, however, one of great interest, and I am sure that I should not be the only one of your numerous readers who would welcome any experiments that Mr. Nalder or others can describe in elucidation of it.

The difficulty, it seems to me, is to arrange experiments of a satisfactory nature in this matter, as molecular movement in iron cannot be produced by the action of a magnet without eddy currents being set up at the same time. How is the heat supposed to result from molecular movement to be separated from that which is caused by induced currents?

It is, I believe, claimed by those who hold that the heat is a result of molecular movement that subdividing the iron effectually checks induced currents, and therefore that the heat in well laminated armatures cannot be ascribed to such currents. As, however, considerable heat is produced in subdivided non-magnetic metals when moved in a magnetic field,

Digitized by Google

and as molecular movements cannot be held to be the cause of this heat, it is evident that even in finely divided iron the generation of eddy currents cannot be overlooked.—Yours, &c., W. M. MORDEY.

April 9, 1884.

## THE SIEMENS DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Whilst experimenting with the Siemens ($W_3$) dynamo the thought struck me that the *iron band* which shields the coils of the armature must divert a great number of the lines of force, so I went to work to prove this experimentally, with the assistance of Mr. Wood (of the School of Telegraphy). We found that when running with the band on at 960 revolutions, if we suddenly took the band off, the speed was immediately brought down to 768 revolutions (the dynamos being driven from a gas engine of 6 horse-power, the governor of which is not in use). We have repeated the experiment, and this time took into account the current in the $D_5$ (exciter) circuit. This we maintained at 16 amperes.

With the band on, in $W_3$ circuit, we got 9·5 amperes on a resistance of 10 ohms (arc circuit). We were running at 970 revolutions. The band was taken off, and the speed fell to 930 revolutions, although the current from the $W_3$ remained the same. We then got the speed to 970 revolutions (with the band off), and now we obtained 9·8 amperes, the current in the field magnets being 16 amperes as before.

Thus we think it would be much better to have a *brass* shield in place of the *iron* one.

Perhaps some one who has a chance will make a similar experiment, as I am sure it is well worth the trouble, and send their results to your valuable paper. I have to acknowledge the kind assistance of Mr. Wood, especially in the latter experiment.—Yours, &c., W. F. BOWEN.

16, Ribblesdale-place, Preston, Lancashire,
April 4, 1884.

## ELECTRIC LIGHTING IN DUBLIN.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your informant (whosoever he may be) who gave you the information which appeared in the last issue of your valuable journal under the above heading has evidently misled you. It is incorrect to say that the directors of the Alliance and Dublin Consumers' Gas Company have discontinued working the electric light either in the face of "orders coming in for new lightings," or in consequence of a "probability of electric lighting making rapid headway, or being fearful of their gas interests." It is equally untrue "that the company discovered they were acting illegally in dealing with electric light under their several Acts of Parliament," the contrary being the case. The fact is that instead of the company having given up electric lighting, electric lighting gave up the company, those who were using it gradually discontinuing its use as the summer approached, and having noticed the company to that effect, until at last the whole of the lighting was reduced to four arc and sixteen incandescent lamps, the proceeds from which I need scarcely tell you would not defray the cost of fuel consumed in producing the electric current. Under these circumstances, you will, I am sure, be of opinion that the directors adopted the most judicious course in discontinuing to supply the current until next autumn, of which due notice was given to their customers. With regard to the "several orders" which, it is alleged, "were coming in," no doubt if the directors at the expense of the company experimented in laying down private installations, including internal fittings for incandescent lighting, orders could be obtained, but this they have no idea of doing, as it is not their intention to follow in the footsteps of the numerous companies who have come to ruin by adopting a similar course. The directors will be prepared to supply the current to any one who will undertake to pay a price that will leave even but a small margin of profit, but they decline to waste money on experimental lighting.—Yours, &c., W. F. COTTON, Secretary.

Alliance and Dublin Consumers' Gas Company,
April 16, 1884.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: From a note in your issue of last week referring to the sudden stoppage of the Alliance (Dublin) Gas Company in supplying the electric light, it would appear that Dublin was by this action on the part of the gas company left without any caterer for the new illuminant. Kindly allow me to say that this is not so.

Inquiries after the new light are numerous, and I am fully convinced that immediately dynamos become less expensive and incandescent lamps reduced in price, isolated installations will become very general. It is prohibitive to have to pay 5s. for renewals of Swan lamps, especially when we consider what frail articles they are, and their liability to be broken in workshops and factories.—Yours, &c.,

J. ANGELO FAHIE, M.S.T.E. and E.

10, Leinster-street, Dublin, April 12, 1884.

## LIGHTNING CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your lengthy and interesting article upon lightning conductors as arranged by M. Melsens suggests the idea that they do (some of) these things better in France than we do in England. But the fact remains that as yet our architects are scarcely educated up to the necessities of the case for having any lightning conductors at all, to say nothing of an elaborate system of protection such as you illustrated in your issue on Saturday. True, the "Lightning Rod Conference" did good work, which I doubt not is fully appreciated by all who are in any way acquainted with the subject, but it is regretted on all hands that they failed to fully appreciate their opportunity when they gave mere generalities where details would have been of value. In the matter of testing lightning conductors—a subject which I have advocated for some years—they contented themselves with merely recommending it, without any details as to how it should be done.

The correspondence on this subject in your columns last year was helpful, but I fear it will be some time before much care is bestowed upon anything beyond the barest means of protection. Colonel Parnell's anti-conductor paper before the Royal Institute of British Architects early this year was valuable in its results in that it provoked a discussion taken part in by Professors Adams, Symons, and Hughes, all of whom were members of the Lightning Rod Conference, and are Fellows of the Royal Society as well. The season is now approaching when thunderstorms may be expected, and since there is no case on record where a properly fixed conductor maintained in an efficient state failed to do its duty, it can only be urged as strongly as possible that conductors should be erected, and those already fixed tested to see that they are still in an efficient condition.—Yours, &c., SAMUEL VYLE.

11, The Terrace, High-street, Walthamstow, E.,
April 16, 1884.

[*Letters from* "Mos Legem Regit," N. M. Arnot, *and others, will be given in our next issue.*—ED. *E.*]

UNDERGROUND WIRES IN NEW YORK.—Senator Daly's Bill requiring telegraph, telephone, and electric light wires to be put under ground by June 1, 1885, in cities of 500,000 inhabitants or over came up for final passage in the New York Senate on the 3rd inst., and was passed.—*Electrical World.*

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The gross earnings of this company for the month ending March 31, 1884, were £6,090.

## LITERATURE.

It is not long since a friend of ours maintained that one of the duties of the technical press was to speak out clearly and distinctly upon all questions of a technical nature that touched upon the public good. It was our duty, he said, to say if the inventions which were being hawked about the City were good or bad or indifferent. We pointed out that while at times it was possible to appraise the value of an invention pretty closely, at others such appraisement could not be made, the value being determined only by an appeal to time and experience.

We have also constant appeals for information relating to books, and here again it is ofttimes impossible to give a short conclusive answer. A book may be good when viewed from one standpoint, while it is utterly bad when viewed from another. Recollecting Bacon's saying that "To use many circumstances ere you come to matter is wearisome; and to use none at all is but blunt," we will endeavour to come to the text of the opening part of this notice. A number of books have recently been published which in our opinion may be called good or bad, according to the point of view from which they are judged. A contemporary, for whose opinions we have great respect, said, in noticing one of these books, "Electricians refuse to see the value of books of this kind, but that which helps to popularise knowledge of a thing which must become popular in its applications, must be doing good, just as the populariser of any branch of science does good by exciting a wider interest in, and therefore paving a wider way to, a more general demand for more complete teaching." We feel quite certain that the writer in the *Engineer* would change his language if the books were on steam engines, and consisted merely of a few scraps of theory taken from any ordinary text book, and a voluminons description, freely illustrated, of engines by Marshall, Ruston and Proctor, Davy-Paxman, and every other known and unknown maker, differing from each other no doubt in details, but hardly in principle. Will the writer undertake to maintain that the compiler of the last school arithmetic or geography is popularising science. Now what, in the name of all that is good, do 90 per cent. of the recently-issued books on electrical matters consist of, if it is not clippings from text-books but half understood by the compilers—pages from trade catalogues and circulars—chapters from periodicals and societies' *Transactions*—thrown together without continuity or evidence of real knowledge of the subject? If any book issued by a man possessed of an average amount of common sense and a tendency to *cacoethis scribendi* is to be esteemed one tending to popularise science, then some of us had better emigrate to a New Atlantis.

> Then the common sense of most shall hold a fretful realm in awe,
> And the kindly earth shall slumber, lapt in universal law.

Then indeed we may become hermits in the higher or lower regions, to be visited occasionally and instructed what to observe. A man cannot popularise that of which he knows nothing, or at the most has merely a parrot knowledge, and it is a great stretch of the imagination to say that half the compilers of these books know the merest rudiments of the science of electricity. They do not—their books prove they do not—and yet they are classed with such men as Tyndall, Proctor, and Preece, who really popularise science. We most emphatically protest against these books being classed as scientific at all—popular or otherwise. They are a kind of trade catalogue. They are compiled to tell people what, when, and how much. But there is not enough true science in them to choke a ten days' old baby. They will be old and out of date in a couple of years. The figures they give as to cost and efficiency will be superseded and worthless in a very short space of time; in fact a few examples might be cited which have been superseded during the time which has elapsed between writing the page and publishing the work. There are from a dozen to a score of these books on electric light and cognate subjects, all containing similar illustrations and descriptions, all framed in the same groove, not one starting with a clear and distinct enunciation of principles, or showing how the principles have been applied in the various machines. The writings of Professor S. P. Thompson and of John T. Sprague, and others we could name, have been a perfect God-send to these compilers, some of whom credit their authorities. Others evidently know as little of the original authorities or some of their statements as they do of the science of electricity. Having delivered our minds upon the question of some recent books, viewed as scientific works, or as popularising science, we may hasten to say that when viewed from another standpoint many of them may be pronounced very good. A piece of pewter viewed as a coin must be pronounced bad, but if viewed as a medal it may be of great excellence. Tyndall's "Heat a Mode of Motion" is an instance of what we understand by the popularising of science, and this is as far removed above the books on electric lighting as the centre of the universe is above the smallest meteor that ever came within the action of the earth's gravitation.

We have said that the public is desirous of knowing what machines and lamps are in the market, what is the cost of such machines, what they look like, what special work they are intended to perform, how they perform that work, and so on. That such books are useful in their way—nay, are necessary—we shall not deny. We prefer rather to welcome such books as filling a void in literature, but must draw the line when the attempt is made to foist them upon the public as scientific books. Todhunter marked an epoch in the history of algebraical books when he published his "Students' Algebra," but surely no one ever thinks of putting the compilers of the hundred and one school algebras, treating the subject as far as simple equations, upon a similar pedestal to that occupied by Todhunter. It may be well to say that the above remarks are general; they are aimed at a whole class, and not against any individual member of that class. For the want of a better name we might entitle the class of books to which we have referred "commercial," though perhaps the majority of people prefer the term "practical." We will now turn to a more congenial phase of the subject, and express opinions upon individual books of the class mentioned, viewing them solely from the standpoint that they are published because of their "practical" or "commercial" character.

---

*I.—The Electric Light in Our Homes.* (Illustrated). By ROBERT HAMMOND. [London: Warne and Co.]

This little book is written in the form of a lecture, and is practically an amplified reproduction of the lectures delivered by the author in many of the largest towns in England during the past year. All who know Mr. Hammond's vigorous, lucid, and amusing style as a lecturer will expect to find these qualities reflected in his book, and they will certainly not be disappointed. The book is pleasant reading from beginning to end. The treatment is very popular, not to say unscientific, but in no instance can it be said to be scientifically wrong. The book is evidently addressed to a class of readers who know absolutely nothing of electricity, and therefore the explanations given are of the most simple nature. The author deals almost exclusively with incandescence lamps, fed by Ferranti machines. The illustration of a Brush arc lamp is introduced, but only to be condemned for domestic lighting. Primary and secondary batteries are also alluded to, and share a similar fate. To guard against a breakdown, Mr. Hammond would not advise the use of accumulators, which he considers costly and untrustworthy, but he would rather duplicate the machinery. This reads like sound common sense; but may not the fact that alternate currents cannot be used for charging accumulators have somewhat influenced the author's opinion?

In a popular book, written by the head of a prominent electric light company, we expect to see a little advertising; but when the author ridicules "some of the well known makers of dynamos" for offering 100 or 250 lighters as their largest machines, and omits to state that other well known makers have for some time past been in the habit of turning out 1,000 lighters and even larger machines, it is evidently unfair to those makers, because the reader is tacitly led to be-

Digitized by Google

lieve that the Ferranti is the only machine which can be made to supply current for a large number of lamps. When speaking of the proposed use of accumulators for house to house lighting from a central station, the author says that this would introduce into the system apparatus almost certain from time to time to get out of order, and that in the present state of the industry it would make central stations for large areas an impossibility. In the face of this prophecy the unsophisticated reader might well ask, how about Colchester, where this very system was specified and is *supposed* to be in successful operation? The book concludes with a very lucid and brief explanation of the provisions of the Electric Lighting Act, 1882, and gives a list of the provisional orders granted by the Board of Trade and presented to Parliament for confirmation during last Session.

---

*II. The Principles and Practice of Electric Lighting.* By ALAN A. CAMPBELL SWINTON. [Longmans.]

This is, perhaps, a more pretentious work than that of Mr. Hammond. In it there is little or no attempt to give pre-eminence to particular makers; all are treated alike. Brief descriptions are given, and the reader left pretty much to draw his own conclusions. Many of the tables are similar to those in this year's *Electricians' Directory*, thus showing once more how similar ideas may present themselves to many minds. We thought certain information would be useful and interesting; Mr. Swinton has evidently thought so too, and and both set about giving it in their own way. The difficulty authors themselves meet with in claiming a position for such books as this is well illustrated in the preface of Mr. Swinton's book. He refers to the "general scientific public" as one of the classes for whose benefit the work is written, and immediately afterwards states his aim to have been "to be easily understood by unscientific readers." The book presents evidence of wide and somewhat desultory reading — we say desultory advisedly. Thus, the gentleman known to most of us as Professor Forbes has distinctly denied the invention of a secondary battery; the Elwell-Parker (not Parkes) battery is Planté's, though commonly called the Elwell-Parker. We shall be glad to hear of an installation where "iron" wires are used instead of copper. Mr. Swinton probably has some particular installation in view when he says, p. 133, "Leading wires of iron are sometimes employed for the sake of cheapness, and also because of their tensile strength." Mr. Swinton's book attempts to describe in simple language the various machines, lamps, and other apparatus that have been devised for use in electric light installations. There is one feature wanting in these books, which an American writer recently termed the "sign of the highest civilisation," viz., a good index. We agree with the American, and maintain that a poor book with a good index is more useful than a better book without an index. We do not know that it is necessary to say more of the work than that the descriptions are generally correct, though at times somewhat short. This latter feature may, however, be readily excused, as much of the apparatus described is only of historic interest.

---

*III. Practical Electric Lighting.* By A. BROMLEY HOLMES, Assoc. M. Inst. C.E. Illustrated. [E. and F. N. Spon.]

This is a smaller work than that of Mr. Swinton, and was published last year. It travels, however, over somewhat similar ground, though there are differences which render it of considerable use. The formulæ are distinctly printed, the paragraphs are rendered clear by typographical arrangements, and attempts are thus made to enable the eye to catch easily the salient points of the subject.

---

*IV. Electricity in Theory and Practice; or, the Elements of Electrical Engineering.* By Lieut. BRADLEY A. FISKE, U.S.N. Illustrated. [New York: D. Van Nostrand. London: E. and F. N. Spon.]

Although the "get up" of the English books we have noticed above is very good, yet when compared with this book from America they are nowhere. We have had some experience during the past quarter of a century in the production of school and other books, and so far as the mere mechanical processes are concerned we think America stands far and away ahead of every other nation. German, Italian, and Spanish books are usually printed on bad paper, with thin covers that are torn off almost as soon as handled. French books are little, if any better. England is in advance, so far as the old world is concerned, while America eclipses all. In the matter of an "index" it would be almost impossible to imagine an American book without one. We hear some mutterings—but how about the matter itself? Usually the German has the thought, the French vivacity, the English solidity, while the American has hybridity. There is not much to choose, however, in books of the kind with which we are now dealing, the same illustrations, descriptions, &c., appearing in books from either country.

The design of Lieutenant Fiske's book is "to form a bridge between the many works written on the theory of electricity and the many books written on its practical applications." In carrying out this comprehensive design the author considers the application of electricity to plating, telephony, telegraphy, electric lighting, and the transmission of power. He seems to have consulted some of the best authorities, and on the whole the arrangement adopted is good, although we could well have spared the pages devoted to the giving of the subject matter of a number of patents. A weak point in all such books, *i.e.*, books containing a large amount of descriptive matter, and one inevitable, is due principally to the fact that the world moves on, and therefore what was new and true at the time of writing is neither new nor true at the time of publication. Thus, in the interval, new and better instruments have probably been devised which are not described. In the work under consideration neither Sir W. Thomson's nor Messrs. Kapp and Crompton's measuring instruments are mentioned. Not a word is said about compound wound machines, though these are rapidly becoming the favourite machines in use, while pages are devoted to meters that never have nor ever will give satisfaction, that have figured principally in papers "read," and seldom with satisfaction in the workshop or practical installation. On the whole, however, the selection of matter is as good as is its arrangement, and credit is due to the compiler for his discrimination.

---

*V. Analytical Summaries of the Patents, Designs, and Trade Marks Act, 1883, and of the Patent Laws of all Foreign Countries and British Colonies.* By A. M. and Wm. CLARK, Fellows of the Institute of Patent Agents. [London: A. M. and Wm. Clark, 53, Chancery-lane. 1884.]

The Act of 1883 has necessarily altered the course of procedure with regard to patents somewhat considerably. Whether the Act will prove all that its designers intended is a matter that time will show; but at any rate the new requirements and the new regulations ought to be brought popularly, succinctly, and properly to the notice of the patenting public. This the authors have endeavoured to do, and have not laboured in vain, for the work is clearly and well written. Of course it is compiled by a firm of patent agents more perhaps with a view to render service to clients than for a purely philanthropic object, but the book bears little trace of the trade circular. Except in the introduction, it concerns itself solely with the work in hand, viz., patents. The chapters are divided into paragraphs, each paragraph having a clarendon sidehead, making conspicuous the subject matter of the paragraph. Added to this there is a very good index, so that great ease is experienced in consulting the work. As the main contents relate almost entirely to matters of fact about which there can be no dispute, the value of such a work depends more on the judicious arrangement of its information, on its clearness of explanation of principles, its description of methods of procedure, cost, &c., than upon opinions. The title description of the subject matter of the paragraphs at the commencement of the chapter on patents will show the method of treatment, commencing with "Patents, to Whom Granted;" "Patents, for What Granted;" then follows paragraphs on "Novelty of Invention," "Duration of Patent," "Date of Patent," "Procedure," "Protection," "Duration of Protection," "Examination," "Advertisement," "Opposition," and so on. Altogether, we think this is one of the handiest of the various works that have appeared on the subject adapted to the wants of the general public.

## THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

### INAUGURAL ADDRESS.

Delivered by Professor W. GRYLLS ADAMS, F.R.S., 10th Jan., 1884.

(CONTINUED FROM PAGE 528.)

There are manifestly two very great defects in gas-engines—1. One-half of the heat resulting from the explosion of the gases passes away through the sides of the cylinder and is thus entirely lost in heating the cylinder. 2. The exploded gas is discharged from the engine at a temperature of about 1,000°C. or 900°C., and so carries away with it a very large portion of the remainder of the heat due to the explosion of the gases.

As pointed out by Sir William Siemens in the discussion on "Gas-Engines" before the Institution of Civil Engineers, this heat should be saved by communicating it to the incoming gases, so that their temperature before combustion should be 1,000°C. instead of 60°C. In 1860, Sir William Siemens had constructed a gas-engine in which compression was employed, and in which the heat from the used-up gases was communicated to the incoming gases, thus carrying out the principle, which with him was of universal application, of using up as far as possible energy which would otherwise escape as wasted energy. In this engine the combustion of the gases took place as they entered a cylinder under compression, without working a piston ; the cylinder could be kept hot, so that the heat of the gases would not be lost.

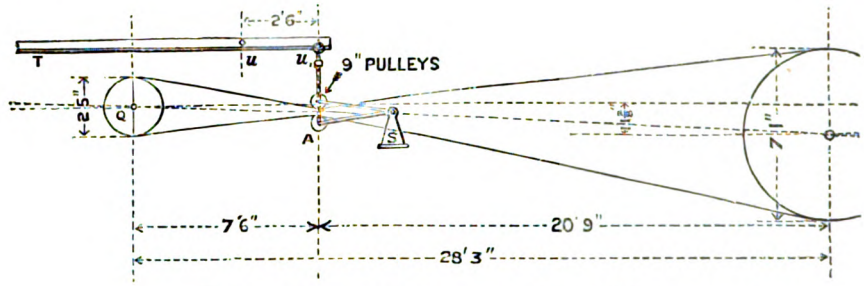

FIG. 4.—Dynamometer used at the Crystal Palace.

The electrical energy in watts = E C or = $C^2 (a+f+r)$. This is converted into heat.

For shunt dynamo machines the total current, C, is the sum of the currents in the field magnets, $C_1$, and in the external circuit, $C_0$. The E.M.F. of the machine $E = C\left(a + \frac{fr}{f+r}\right)$, and the electrical energy in watts, E C, since $C = C_0 + C_1$. The electrical energy spent in heating the armature $= C^2 a$. The electrical energy or heat in the magnets $= C^2{}_1 f$. The electrical energy in the external circuit $= C^2{}_0 r$ where $p = C_1 f = C_0 r$.

The work applied to the dynamo machine must be determined by a transmission dynamometer (see Fig. 4). The *electrical efficiency* of the dynamo is the ratio of the total electrical energy to the total energy absorbed, deducting the energy spent on the friction of the driving shaft.

Of the total electrical energy produced, one portion is spent in heating the wire of the armature and field magnets, and is therefore wasted ; the remainder is spent on the external circuit, and is the only portion which can be converted into useful work. The ratio of this external electrical energy to the total energy absorbed may be termed the *useful electrical efficiency* of the machine. In order to determine the efficiency of a machine (1) the internal resistances of the armature and field should be determined, (2) the difference of potential at the terminals, (3) either the current or external resistance. Then the external resistance or the current respectively may be deduced from Ohm's law, and the electrical energy in *watts* may be determined.

In the Crystal Palace experiments (see *supplementary note* and Fig. 5) the *difference of potential* at the terminals was found by charging a condenser from them and discharging it through a high-resistance galvanometer, and

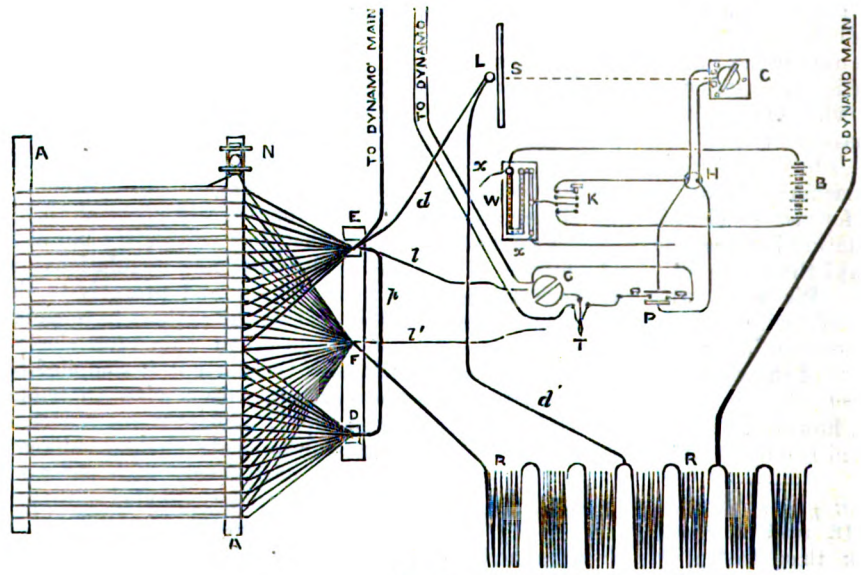

FIG. 5.

*Efficiency of Dynamo Machines.*—Having considered the efficiency of steam and other engines, by means of which heat may be converted into energy of motion, I wish now to consider the conversion or transformation of mechanical work into electrical energy by means of dynamo machines, and to illustrate my remarks by the results of the experimental tests of dynamo machines made at the close of the Crystal Palace Exhibition.

In this, as in other branches of the subject, accurate measurement and practical applications react on theoretical investigations in supplying the instruments and the means of progress. The dynamo machine has supplied the means of testing and working out its own theory ; and even the Edison machine may be improved when the theoretical and practical knowledge of a Hopkinson are brought to bear upon it.

In the electric circuit of a dynamo machine with an internal resistance, $a$ (the armature) and $f$ (the field), and external resistance $r$, the whole arranged in simple circuit, we have, by Ohm's law, $E = C(a+f+r)$, and the difference of potential, $p$, at the terminals of the machine, $p = Cr$.

comparing the deflection with the deflection obtained by charging the same condenser from a Clark standard cell. *The current* was obtained (1) by charging the condenser from the extremities of a given resistance consisting of several branches forming part of the circuit. (2) By means of a tangent galvanometer, N, placed in one of these branches whose resistance was known. The work absorbed per second was determined, and is expressed in watts, so that it may be readily compared with the electrical energy.

Let me work out one case completely, so as to show the methods adopted to determine the efficiency of each machine.

I will select one of the three Bürgin machines (the $C_3$ machine) submitted by Mr. Crompton. In the $C_3$ machine the resistance of the armature (cold), $a$, = ·528 ohm ; the field magnet, $f$, = ·435 ohm ; the difference of potential, $p$, = 92·8 volts ; and the current, 31·18 amperes.

To determine the difference of potential at the terminals. Let $d$ be the deflection of the galvanometer on discharging a condenser after charging it from the standard cell, let B be the mean deflection on discharging the

A Absorbed power appearing electrically. B Proportion of electrical energy in external circuit. C Absorbed power appearing in external circuit.

condenser after charging it from the machine terminals, $t$ the ratio between the values of the shunts employed; then $p = \frac{t\,B}{d} \times 1{\cdot}457$ volts. In this case $t = 10{\cdot}47$, $B = 219{\cdot}1$, $d = 36$; hence $p = 92{\cdot}843$ volts.

To determine the current C in the external circuit:—

(1) By the condenser. Let $b$ be the mean deflection on discharging the condenser after charging it from the terminals of the tangent galvanometer circuit, and $m_1$ the resistance (hot) of wires on the frame; then $C = \frac{b \times 1{\cdot}457}{d\,m_1}$. In this case $b = 148{\cdot}6$ and $m_1 = {\cdot}158$; hence $C = 38{\cdot}064$ amperes.

(2) By the tangent galvanometer. Let $\theta$ be the deflection of the tangent galvanometer, $k$ its constant, $g$ its resistance, $m$ the resistance of wires used in the experiment; then $C = \frac{\tan.\,\theta \times k \times g}{m_0}$. In this case $\theta = 47{\cdot}67°$, $k = 3{\cdot}469$, $g = 1{\cdot}559$, $m = {\cdot}155$; hence $C = 38{\cdot}30$ amperes.

The mean value, $C_0$, from these two results is $38{\cdot}182$ the external resistance, $r$, $= \frac{p}{C_0} = \frac{92{\cdot}843}{38{\cdot}182} = 2{\cdot}4316$ ohms, the internal resistance $(a+f)$ of armature and field when hot from the current is $1{\cdot}02$ ohm; hence the whole resistance is $3{\cdot}4516$ ohms, and the whole electromotive force of the machine $= C_0(a+f+r) = 131{\cdot}79$ volts.

Now with regard to the efficiency of this machine, the number of watts $= C^2(a+f+r) = 5{,}031{\cdot}5$, and the electrical horse-power $= \frac{C^2(a+f+r)}{746} = 6{\cdot}7461$.

Now the actual horse-power applied as measured by the dynamometer, deducting the horse-power required to overcome the friction at the driving speed, is $7{\cdot}7018$; hence the electrical efficiency of the machine, *i.e.*, the fraction of the power applied which appears as power in the shape of electric currrent is $\frac{6{\cdot}7461}{7{\cdot}7018} = {\cdot}8759$ per cent. Of this, the fraction which appears in the external circuit is the ratio of the external resistance to the total resistance $= \frac{2{\cdot}4316}{3{\cdot}4516} = {\cdot}70448$. Hence the external or the useful electrical efficiency is $61{\cdot}7$ per cent.

On comparing the two methods of measuring the current, we have the following results:—

*By Condenser method.*

$C = 38{\cdot}064$.

$r = \frac{92{\cdot}843}{38{\cdot}064} = 2{\cdot}4391$.

Total resistance $= 3{\cdot}4591$.

E.M.F. $= C \times 3{\cdot}4591 = 131{\cdot}67$.

Units of work, or watts, 5012.

Electrical H.P. $= 6{\cdot}7191$.

H.P. applied, deducting for friction, $= 7{\cdot}7018$.

Electrical efficiency $= {\cdot}87241$.

The fraction of this appearing in the external circuit $= {\cdot}70513$.

External electrical efficiency $= {\cdot}6152$ or $61{\cdot}52$ per cent.

Digitized by Google

*By Tangent Galvanometer.*

C = 38·30.

$r = \frac{92·843}{38·30} = 2·4241.$

Total resistance = 3·4441.

E.M.F. = 131·91.

Watts = 5053.

Electrical H.P. = 6·7731.

H.P. applied, deducting for friction, = 7·7018.

Electrical efficiency = ·87943.

Portion in external circuit = ·70383.

External electrical efficiency = ·6190 or 61·90 per cent.

Thus the difference in the two methods is only about two-thirds per cent. on the efficiencies.

For machines with a separate exciter, such as the Maxim machine and the H Gramme machine, the same methods were adopted for finding the current and the potential at the terminals, but in the case of the exciter the current was obtained from the potential at two points, and the resistance measured between them by the Wheatstone bridge immediately after the experiment whilst the portion of the current was still warm.

In shunt dynamo machines the potential was determined at the terminals, and the current in the field magnets determined from their resistance measured (warm) by the Wheatstone bridge immediately after the experiment. The current in the external circuit being determined by the same methods as before, and the external resistance when running deduced from this current. In this case the total resistance is the resistance of the armature together with the combined resistance of field and external circuit. The total current, C, is the sum of these two currents. Hence the E.M.F. of the machine $= C\left(a + \frac{fr}{f+r}\right)$, where $C = C_0 + \frac{p}{f} = C_0 + \frac{tB}{fd} \times 1·457$.

It will be seen from the table of efficiencies of these dynamo machines (see p. 547) that there are several which are capable of converting into electrical energy more than 80 per cent. of the energy absorbed, and that some convert more than 90 per cent, so that as converters of energy they are very efficient machines. But in some of these the internal resistance is so high as compared with the external that there are only five which give more than 80 per cent. of their electrical energy in the external circuit—*i.e.*, the useful electrical energy is only 80 per cent. of the total electrical energy.

The Edison machine, with thick copper rods or bars in the armature, converts into electrical energy 91 per cent. of the absorbed power, and of this amount 91 per cent. appears in the external circuit, so that $\frac{91}{100} \times \frac{91}{100}$, or ·83 of the absorbed power, appears as useful electrical energy in the external circuit.

Of the others there are only three, viz, the B Gramme, the Maxim, and the Weston, which convert over 70 per cent. of the power applied to them into useful electrical energy.

After discussing the Bürgin $C_3$ machine so fully, it is only fair to Mr. Crompton that I should state that since these tests were made he has entirely altered the internal resistance of his machines and their general arrangement, and has greatly improved their total efficiency as well as their useful electrical efficiency.

Through the kindness of Dr. Hopkinson I am able to give you the latest information with regard to the Edison-Hopkinson dynamo machines.

One of these was tested by Mr. Sprague after our tests were made at the Crystal Palace, and he found that 94 per cent. of the absorbed energy appeared as electrical energy. A large Edison-Hopkinson machine on board the "Oregon" supplies 520 Edison A lamps with a current of ·72 ampere each, and the E.M.F. is 107 volts, so that the amount of useful energy is 40,000 *watts*. The resistance of the field-magnets is 17 ohms, and of the armature less than ·01 ohm when warm; hence the current in the magnets is about 6 amperes, and the total current in the armature 380 amperes. The energy spent in heating the field magnets is $\frac{107^2}{17} = 670$ watts; in the armature is $380^2 \times ·01 = 1{,}444$ watts; thus only 6 per cent. of the electrical energy is spent in heating the machine, and 94 per cent. of the electrical energy appears as useful electrical energy in the external circuit.

Thus $\frac{94}{100} \times \frac{94}{100}$, or ·88 of the power absorbed, is converted into useful electrical energy. Thus, the 83 per cent. of the Edison machine has been raised to 88 per cent. by the improvement introduced into it by Dr. Hopkinson.

In considering these efficiencies of dynamo machines, as well as all efficiencies which have been determined up to the present time, it is important to remember that they depend upon the value of our unit of resistance in two ways—(1) directly, because we are measuring resistances, and (2) indirectly, because in measuring electromotive forces we take as our standard a unit of electromotive force which depends upon the value of our unit of resistance.

Thus Clark's standard cell is said to have an electromotive force of 1·457 volts, but this number is derived from the B.A. unit of resistance, which several experimental tests by Lord Rayleigh and by others have shown to be ·9865, or more than 1 per cent. below the theoretical unit of resistance. The E.M.F. of Clark's cell and of standards of E.M.F. must be altered to the same extent to suit the Rayleigh ohm. Hence all efficiencies of dynamos which have been hitherto determined must be more than 1 per cent. too high, and should be reduced in the ratio of ·9865 to 1.

(TO BE CONTINUED.)

## TABLE OF TESTS OF HEINRICHS' DYNAMO, TAKEN MARCH, 1884.

*Series Wound Dynamo Machine.*

OBSERVATIONS.—The resistance of the dynamo depended of course upon the amount of current produced and upon the time the machine had been kept running. According to our views, the commercial efficiency of the machine should be calculated with the horse-power for the machine running empty included, the commercial percentages would then be less (*see* Column 4), but in recently made tests of well-known machines this extra horse-power has not been taken into account, but, as will be seen, we have given both calculations. The formula for the brake $\frac{n \times L \times x}{5252}$ where $n$ is the number of revolutions per minute, L the length of the lever in feet, and $x$ the weight inclusive of the lever and scale. Where a wire resistance formed the external circuit we have given the current and total measured resistance; when lamps were employed we give the E.M.F. and current, the external resistance of course being calculated. We may add that the machine did not on any occasion show any noticeable sparking, and the peculiar construction of the armature and pole pieces appears admirably adapted for securing the highest degree of ventilation. The mean diameter of the Heinrichs armature is 8½in., the periphery speed therefore may be easily calculated. The weight of wire (No. 16 B.W.G.) in the armature is stated to be 16½lb., and on the field magnets (No. 10 B.W.G.) about 80lb. The above tests were repeated so often that we are convinced they might be readily reproduced at any time. On the 10th of March the following test was made:—Nine straight carbon lamps were arranged in three parallels of three each, the current flowing was 33 amperes, the machine running at 1,000 revolutions. After running about one hour the dynamo became slightly heated, and the experiment was then discontinued for that reason. All the above tests made with less than 30 amperes.

## HEINRICHS' DYNAMO.

The following report of Messrs. Alabaster, Gatehouse and Co. has been forwarded to us :—

At your request we have made an extended series of tests on your series wound dynamo-electric machine, which, we understand, is the first one constructed by you as long ago as the year 1881-82. These experiments were carried on at intervals during a period of five weeks or so, and a very large number of observations were made.

We desire to preface our results with a few preliminary remarks on the apparatus employed by us. We had at our command, for the sake of comparisons, three voltmeters and one ampere-meter of the Ayrton and Perry design, a voltmeter devised by Capt. Cardew, and two Siemens electro-dynamometers. Two Wheatstone bridges by different makers were used for checking resistance measurements, and several mechanical speed indicators, checked by Kempe and Fergusson's electrical indicator, enabled us to take accurate observations of speed.

After a large number of preliminary tests we selected for our readings of electromotive force and current an Ayrton and Perry voltmeter (which was several times compared during the course of the experiments with a standard electromotive force of known value) and a Siemens electro-dynamometer. The resistance of the circuit, the external portion of which was made up of a number of coils of thick copper wire cotton covered, was measured after every experiment. Calculations of the electromotive force from the current and resistance, or current from electromotive force and resistance, invariably very closely corresponded with the results indicated by the readings on the respective instruments, thus assuring us that our electrical instruments could be well depended upon. For horse-power measurements we employed a Morin dynamometer and a Prony brake.

The Morin dynamometer was fixed so that it drove the dynamo machine. This arrangement was adopted to avoid any errors which might be occasioned by the varying friction of intermediate countershafts, slipping of belts, &c. We were forced, however, to abandon any calculations of horse-power from this dynamometer since the centrifugal force of the moving parts of the instrument appeared to interfere very seriously with the results, when driven at a comparatively high speed.

The *constant* given for the machine is also evidently erroneous for varying speeds, so we were compelled to have recourse to the Prony brake, using the Morin apparatus merely as an indicator. Thus, the Morin indicated a certain pull when the dynamo was running at a given speed and producing, say, five electrical horse-power. The same pull at the same speed would then be *reproduced* by applying the Prony brake to the dynamo, and the horse-power *absorbed* by the dynamo could then readily be ascertained. A large number of tests were taken in this manner, which appears to us to be a most satisfactory method ; indeed, the only one to produce accurate results. We may add that the Morin dynamometer calculations agreed fairly well with those taken from the Prony brake when the speed did not exceed 1,000-1,100 revolution. With the latter apparatus, however, we dispense entirely with springs, irregularities from centrifugal force, loss in transmission by belting, &c. We append a table of several of the tests, which were many times repeated :—

The construction of the Heinrichs machine, which is simple and strong, appears to be particularly well adapted to secure a minimum loss from heating effects, the influence of the so-called Foucault currents, &c. When arc lamps were employed as the external resistance, we made use of either a number of straight carbon lamps, or a single circular carbon lamp of the Heinrichs type with the addition of wire resistance. Although no photometric measurements were made we cannot but think that the Heinrichs lamp should stand foremost amongst those now in general use, as from its peculiar construction the whole of the luminous rays are thrown downwards.

All readings were taken at as nearly as possible the same instant, this being rendered necessary by some considerable irregularity of engine speed. The observers at all the instruments were frequently changed about in order to ensure every possible means of reducing error.

H. Alabaster, Gatehouse and Co.

## HAMMOND ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).

The third ordinary general meeting of the shareholders of this Company was held on the 17th inst., at the works, Appold-street, Finsbury, under the presidency of Sir Charles Lawrence Young, Bart.

The Secretary (Mr. P. A. Latham) having read the notice convening the meeting,

The Chairman said : You will, I presume, gentlemen, take the report as read, and I can only say that I heartily wish it were pleasanter reading. At the same time I am bound to say that there is room for satisfaction that it is not very much worse. We are unable to show this year a profit upon our working, in which respect we are unfortunately in the same position as other electric lighting companies. We have, however, secured a good deal of business, and obtained for ourselves a substantial position, the beneficial results of which will, we may not unreasonably hope, enable the directors to have a more agreeable report to give you on the next occasion. Mr. Hammond is anxious to address you on the details of the accounts, and I desire to confine my remarks to the policy which we propose to pursue. Hitherto the business of electric light companies has apparently been very much of the hand-to-mouth order. Between eighty and a hundred different companies have had their inception in the last three years, and without stopping to inquire how many have gone from the prospectus stage to actual working results, it is enough to say that those that have obtained capital and survived the struggles of infancy have engaged in competitive action which gives everything for next to nothing, and the article provided has in many instances materially suffered in consequence. But the net result unquestionably has been that the business has been extensively advertised, and that the public, which in domestic improvements is always hard to move, has begun to regard electric lighting with a serious interest, and to understand that it means something more permanent and more generally profitable than a speculation in shares. Had it not been for that perfervid enthusiasm which chose to believe a couple of years ago that large profits were to be made with little time and less trouble the electric lighting business would be in a more substantial position than it is to-day. There always comes a cold re-action after the white heat of enthusiasm, and after leaps and bounds we find ourselves on a dull level, and we may be thankful if we have not to retrace our steps entirely. What, perhaps, we have suffered from more than anything else is from the variety of systems that have been born and lived, and the number that have been born and died. Those with whom we have reasonably expected to do business on a large and therefore profitable scale have not unnaturally said : "So many experiments in the field of electric lighting are being perpetually made, chiefly at the cost of the experimentalists, that we prefer waiting till the best system has been proved, and the best and cheapest results obtained. Then if you can provide us with that system and those results we shall be happy to talk to you, unless you would like at your own cost and risk to show us what you can do, and then perhaps, if we like it, we will take the plant over at the end of a year at cost price." This is the kind of business, gentlemen, we have had to deal with, and you will probably agree that we have had quite enough of it. I do not mean to say that we have not in hand certain installations the benefits of which will accrue to us in the current year, but in so many cases we have had to work under such adverse circumstances that profits have been eaten up by working expenses. The bright side to the position is that we have undoubtedly laid a solid foundation for the future, and that the sovereigns we have expended have established a business. That business has now to be built up, and we conceive that the most remunerative shape that it can take will be, not in isolated installations here and there, for which there is such abundant competition, but in securing districts and supplying electricity from a central station, just as gas is supplied. An urban population wants to be supplied with domestic illumination with as little domestic trouble as possible. The action of gas, deleterious to health and destructive to decoration, has, as you are all aware, compelled thousands upon thousands of householders to have recourse to mineral oils and candles for lighting drawing rooms, dining rooms, libraries, and bed rooms, and if old lamps are to be exchanged for new ones it must be upon the condition that the new ones give more light and less trouble. Therefore, there is good ground for thinking that neither primary nor secondary batteries will solve the problem of house-to-house lighting, eminently useful as they may be elsewhere, but that a direct supply of electricity from central stations, which can be turned on and off from each lamp, as gas from gas meters, and which can be paid for on the same principle, viz., according to the amount consumed, is what the public want, and I make bold to say that the company which first achieves this great result is the one which will give splendid pecuniary recompense to its proprietors. The report of the directors has sufficiently indicated to you their view of the question, but as it is hopeless to expect to achieve any great success in this direction without adequate capital at command, we are going to ask you to pass the resolutions of which notice has been given, which will give the Company power to raise further share capital, and to make a new departure, as it were, unweighted with a load of paper liability. Our first idea was to ask for powers to raise fresh capital by debentures without touching the shape of the original capital ; but on consideration the scheme did not commend itself to us, as it would interfere with the dividend prospects of the shares, and further, if the success which we confidently anticipate attends our first undertaking in house-to-house lighting on a large scale, the demand will be so great that we can only measure the future capital of such an undertaking as this Company ought to become by the millions of the great gas corporations. You see under this roof the nucleus of our work. We are carrying out contracts at Brighton, Birmingham, Nottingham, Norwich, Middlesbrough, Manchester, Cambridge, Eastbourne, Hastings, and other centres, and we hold a provisional order for Hampstead, and some of you may have seen, by an answer given by the President of the Board of Trade in the House of Commons just before the recess, that the Hampstead order had been specially extended, or it would have expired in February last. Gentlemen, we attach great importance to this provisional order, and if you accept the resolution we are submitting to you to-day we shall shortly be in a position to commence work in that district. The piece of land for the erection of the works has been selected, and the first of the large dynamos it is proposed to use is now in hand. As you see by the report satisfactory local support has been promised, and the promises are likely to become more numerous and substantial when we prove to the residents that we mean business and they see that our arrangements are actively progressing. At the present moment we must not allow ourselves to be discouraged by the appearance of our balance-sheet. The one error which I will admit in the management of this Company is that we did not start with a far larger subscribed capital, though there is room for the argument that a large available capital is really of more importance to-day than it was two years ago. Then we had no precedents to guide us—there was nothing by which to gauge our probable rate of expenditure, our position was necessarily tentative, our business was simply inchoate. I venture to say that no electric lighting company has made such solid progress as we have made. And if we have not yet achieved a great pecuniary success, why, after all, what are two years in

Digitized by Google

the history of such a work as we have in hand? Had we, indeed, any right to suspect, or even to hope for, greater results than have been obtained in so brief a period? Do not be frightened by the gaseous folk who are so loudly proclaiming that electric lighting has never yet been made to pay. Where would the gas companies be if they had to work under the same conditions?—where would their huge profits be if they only had to light up a few squares and streets, with an occasional manufactory or hotel? Give us half the opportunities that they have, and there will be a very different tale to tell. The opportunities, gentlemen, will come; our business is to be in a position to make use of them. But we must have patience. Impatience is almost certain to be followed by failure, and the history of successful enterprise is to be found in the records of those who knew how to wait and to persevere. I beg to move that the report and accounts be adopted.

The MANAGING DIRECTOR (Mr. Robert Hammond) seconded the motion. In the course of his observations he remarked that however strong their faith might be in the ultimate future of the business, they were unfortunately face to face that day with a very serious loss. He, however, endorsed the views expressed by the chairman that what had been done in the past had, after all, founded a solid business. With regard to the accounts, it seemed to him that, whether in a private enterprise or a public company, there was only one way in which a balance-sheet should be made up—namely, that on the one hand every liability which could possibly come upon the company should be distinctly weighed and stated, and that every asset should be a solid asset, an asset representing actual value. He was able most strongly to state that there was not an item in the balance-sheet before them which had not been regarded in that light. If it were necessary to make a new departure in the Company, that departure would be of very little use if the figures were not dealt with in a very close and careful manner, and the principle underlying the accounts was that every single item on the asset side of the accounts should be on that basis that if they had to choose they would rather be buyers than sellers of the article at the price stated. At considerable length Mr. Hammond then reviewed and commented on the chief items of the balance-sheet and profit and loss account. He stated that the item of £3,228 under the head of stocks represented merely the cost price to the Company of the raw material which was being used in the contracts in progress, nothing being taken into consideration in the accounts for the ultimate profit on this business. He was glad to say as to this point that there was not a single item there which did not represent a contract on which a profit depended. As to the contract with Messrs. Colman at Norwich last year they put up 300 lights, and the work had been so ably carried out that they had received authority to increase the wiring to such an extent as to run 1,000 lights instead of only 300. This would enable them to test practically the Ferranti machine, and the firm would pay them for the work done in the way of the wiring. The stocks on hand for sale are valued at £18,648, and included in the amount here was a considerable sum for the Brush machines which they bought in the course of the year before last, a certain portion of which they had still on hand. He had no doubt that the large dividend paid at the outset by the Brush Company had led to the idea throughout the country that large profits were being made, and that idea had caused a cessation of the orders for the Brush machines, which, however, were being gradually used; and he trusted that next year they would be able to show a considerable diminution in the item of stocks on hand for sale. The plant at the various places they had valued with the same care, refusing to take into account any profit that might arise on the work. Where a loss was being sustained, as at Chesterfield, they had given notice not to renew the contract. At Brighton they were doing some very good work. The Corporation of Brighton had to decide in a fortnight whether they would exercise the provisional order they had obtained. Meantime the Company had a central station at Brighton, and any one there could obtain the current for the use of the electric light. The experience of the Company at Brighton showed how universal would be the use of the electric light if it were possible to get it from a central station and supply it in the same way as gas was supplied. It was, however, impossible to supply it where only £4,000 or £5,000 was in the station at the same low price as could be charged if £100,000 were in it. As to the factory at Appold-street, everything about the place was in a form enabling the work to be carried out in the best manner, and everything connected with electric lighting was made there. The incandescent lamp factory at Bermondsey-street was working in an eminently satisfactory manner. The college was also working very satisfactorily, and was a paying experiment. They felt they had in training for their work a set of young gentlemen who would do the Company immense credit and be of great service to them in the future. Although practical knowledge of electricity was being imparted to them, they were now working the undertakings of the Eastbourne and the Hastings Companies, both of which had received considerable local support, and there would be an immense amount of business done at both places should the working be conducted successfully for the next two years, during which this Company would have the control. One could say of the failures which had occurred that this had happened where unqualified persons had had the management of affairs. As to the deposit at Messrs. Hoare's, *re* the Donnithorne and Liardet agreement, he stated that stringent tests had been applied by the Company to the accumulator which those gentlemen brought to them some time ago. They felt very positive as to their position in connection with this accumulator under the agreement made, and he looked on the deposit in respect of it of £5,695 as a perfectly good asset, and one which ought very soon to be returned into their pockets. They had still Brush machinery to the value of £15,000 to take from the Anglo-American Company under their recent agreement with that company, by which all differences between them had been settled. The shares in sub-companies, standing at £2,820, had reference to the shares they held in the Hastings and Eastbourne Companies. Passing to the profit and loss account, he referred to the receipt of a letter from a shareholder who stated that he was the chairman of a Liverpool bank, and expressed the pleasure which the letter had given the directors. Mr. Hammond then went through the various items on the debtor side of the profit and loss account, and expressed his belief that the time must come when there would be an amalgamation between this Company, the Anglo-American Company, and the Swan and Edison Company. At no very distant date he hoped there would be in operation a working arrangement between them by which they would get a profit on work they did, where now they very often sustained a loss. So far as the Hammond Company was concerned they were determined to take no contract unless it left them a fair working profit; and if the other companies followed suit they would very soon see electric lighting in a solid position. Very heavy expenditure had had to be incurred by the Company in making the electric light popular throughout the country, but they now felt that the aim they had had been accomplished, and that the Company was now known. They had closed every branch they had had; the expenditure on advertising and experiments would be very considerably reduced in the future. The Company was now really suffering from the mania of eighteen months ago when apparently every one was going to have the electric light; but having passed through that experience it was not likely they would have to pass through it again. Reverting to the letter to which he had referred, he said he believed that the total of £32,860 on the debtor side of the profit and loss account might very well, as the writer had said, be reduced in future to £7,000, and that they might thus be able to regard 75 per cent. of the total stated as exceptional expenditure. He then went back to the balance-sheet, and mentioned the reasons which had induced the directors to deal with the item of goodwill and patents on the credit side, as they had done, observing that he did not regard the amount by any means as lost. The directors felt that the Company was thoroughly able to cope with the house-to-house supply of the electric light, and supply it in the same manner as gas was supplied. Before, however, they could obtain the necessary capital to enable them to do this work it had been felt that the alterations as to the existing capital should be made. He then described in detail the nature and effect of the proposed changes, and afterwards stated, in conclusion, that having treated the accounts in the manner recommended they would be left in the position of having on the credit side of the balance-sheet a matter of £97,000 in absolute tangible assets, and having all their patents to the good. On the other side, their liabilities, including the new issue of shares, would leave them with a reserve fund of some £8,000, which would be quite sufficient to deal with any contingency that could possibly arise. The shares at £1 10s. would represent not only tangible assets, but £8,000 reserve fund to the good, and the whole of the prospects of the business, in founding which they had spent so much. It was not proposed that the new issue of shares should take place immediately, but they asked powers to make the issue whenever they considered a favourable juncture presented itself. Mr. Chamberlain stated the other night in the House of Commons that only two of the provisional orders which were granted a year ago were now in existence, and of these two one of them was granted to this Company, for Hampstead, and one was granted to the Pilsen Joel Company. They were in the position of being able to apply the money coming in to house-to-house supplies, and he felt that they were ahead of any other company. Corporations throughout England were in correspondence with them, but all the corporations that had voted money to obtain provisional orders were waiting for some company to take the initiative. Some one would have to spend £100,000 or £150,000 in giving the house-to-house supply, and that money would be obtained by the changes which the directors now recommended the shareholders to assent to.

A brief discussion followed, and, in reply to Mr. George Herring,

The CHAIRMAN stated that the new shares would not be issued under par.

Mr. HAMMOND stated that of the calls of £28,000 there appeared as an asset at the head of the balance-sheet £14.000. The rest was in the business. As to the amalgamations carried out by the Company last year, they felt that they were the first steps towards a general amalgamation.

The CHAIRMAN then put the motion, which was carried unanimously.

---

An extraordinary meeting was then held to consider the following resolutions:—1. "That the nominal capital of the Company, which now consists of the sum of £330,000, divided into 66,000 shares of £5 each, be increased to the sum of £525,000, and that this amount be divided into 350,000 shares of the nominal value of £1 10s. each" 2. "That 50,123 shares of the nominal value of £1 10s. each, forming part of the said capital of £525,000, be issued as fully paid up, and that the same be applied in manner following, that is to say: (*a*) 40,133 of the said £1 10s. shares rateably to the present holders of the 40,133 ordinary £5 shares in this Company. (*b*) 7,990 of the said £1 10s. shares to the holders of the 15,980 deferred £5 shares in this Company, and 2,000 of the said £1 10s. shares to the holder of the founder's shares in this Company." 3. "That the directors be empowered to enter into such agreements or contracts as may be necessary for the carrying out of all or any of these special resolutions, and to issue and allot the balance of the authorised nominal capital of the Company from time to time, on such terms and conditions as they in their discretion may think fit." 4. "That an indenture bearing date the 19th day of March, 1884, and made between the Hammond Electric Light and Power Supply Company (Limited), of the one part, and Robert Hammond of the other part, be and the same is hereby ratified and confirmed."

All these resolutions were passed except the last, as to which it was felt by one speaker that it would be better for Mr. Hammond to be paid by a percentage of profits rather than by a salary of £1,000 a year (the

Digitized by Google

effect of the indenture referred to in the resolution). An amendment was moved to this effect.

The CHAIRMAN pointed out that Mr. Hammond gave the Company all his time, and rendered them exceptional and invaluable service. In favour of the amendment only six hands were held up, fourteen being against it, and subsequently the resolution was carried *nem con.*

The retiring auditors were afterwards re-elected, and the meeting then terminated.

## FAURE ELECTRIC ACCUMULATOR COMPANY (LIMITED).

The adjourned general meeting of the above Company was held on the 16th inst., at the Cannon-street Hotel. The meeting had been adjourned by the directors from time to time until the date mentioned, none of them, however, attending, as was stated at the outset of the proceedings. Mr Harcourt Turner was voted to the chair. A meeting of the shareholders, convened by Mr. Turner, was held on the 7th inst., as reported in our last issue.

The CHAIRMAN stated that since the meeting last Monday week the secretary had been in communication with the two remaining directors as to the present meeting. He then read the letters which had been received from these gentlemen—Baron de Maubeuge and M. Armieux—both of whom wrote from Paris resigning their seats at the Board. The chairman afterwards alluded to the following letter, which had been addressed to the shareholders by M. Philippart, who wrote under date Paris, April 10, and signed himself "ex-director and chairman":—"My bankruptcy has brought about disastrous consequences to our common interest; it has indeed carried in its train, and rendered inevitable, the bankruptcy of the companies: La Société la Force et la Lumière; French Electrical Power Storage Company (Limited), and French Metropolitan General Electric Company (Limited). Deprived of my co-operation my colleagues cannot, under these circumstances, do otherwise than place their resignation in your hands. As for myself, although I am vanquished, I continue to remain here on the breach, for I cannot desert the interests which have been confided to me, and which are mingled with mine; although alone, I am still able to protect them. If my work and my help can be of any avail to you in Paris and in France, I can, however, do nothing in England beyond giving you my best advice upon what I deem there remains to be done by you in our common interest. It must not be forgotten that the origin of our ruin dates from the time, just two years since, when your directors refused to prosecute the English Electrical Power Storage Company, who had pirated our patents; the origin of all the evil arises therefrom, and to-day those who had pirated our patents having become everywhere the masters, and benefiting by events more and more unfortunate, now pretend not only to hold us well and duly dispossessed of our English patents, but even to retake gratuitously the French patents without making restitution for the considerable sums which we have paid them. Under these circumstances there is in my opinion only one thing to be done; it is to put at the head of your Company those notable men who were its founders. Upon them is it incumbent to reassume the management of your interests, and it is their duty to agree to do so. Our Company has no debts, and it has still a considerable amount to call up on a part of its shares; herein are sufficient resources for claiming our English patents. That is what your directors ought to do. On my part, here in Paris and in France I shall contest with our common adversary the French patents, and I have no doubt of success, relying upon our right and upon French justice." The chairman stated that he would say nothing about this letter until the committee, which was appointed at the meeting on the 7th inst.—and the confirmation of whose appointment he now suggested—had investigated the affairs of the Company. There were now no directors of the Company. The committee consisted of the following gentlemen:—Sir Charles Clifford, Mr. Edward Ponsonby, Mr. W. D'Oyly, Mr. H. Rankin, himself, Mr. L. A. Solomon, Mr. Grenfell, and Mr. W. W. Duncan. There were thus eight members of the committee, and if they all attended there might be a division of opinion. He did not know whether under these circumstances the meeting would wish the number to be increased or decreased by one.

A SHAREHOLDER suggested that the chairman should be given a casting vote.

In reply to questions by shareholders,

Mr. CAMPBELL (the solicitor) stated that as far as he had had anything to do with the exchange of shares under the terms of M. Philippart's offer the matter had been completed; and he believed that everything that was necessary to be done had been legally done. He did not take counsel's opinion on the matter, and he was not aware that there was anything on which to consult counsel.

Mr. HERBERT CANNING (the secretary), in further reply to one of the questions, stated that he knew that under M. Philippart's offer a certificate for one £10 fully paid share in the Company was given in exchange for two shares of £2 each in the Company. In every case where shareholders had agreed to accept the exchange these certificates were given to them.

Sir A. J. OTWAY, M.P., said he thought that some misapprehension prevailed in the matter, and he might therefore remind them of the circumstances in connection with the exchange. Contrary to the advice which he (Sir A. Otway) gave the shareholders, they agreed to accept the offer of M. Philippart. Although this had relieved him of all responsibility towards them, he stated that he would not leave the Board until every shareholder had had an opportunity given him of relieving himself of any liability under his shares. He told M. Philippart that this was his intention, and the great bulk of the shareholders had accepted the offer which had been made to them, and had relieved themselves of any liability. Some of them, however, had not done so, and the chairman was among the number; and on behalf of those gentlemen he thought the shareholders should make an effort. He thought it would be most unwise for them to regard the concern as utterly destroyed, and give up all idea of recovering the property they really possessed. He would not give much for their chance of recovering any cash, but they had patents in France and England. He suggested that the committee which had been appointed should make an investigation of the affairs of the Company, and then depute Mr. Campbell to go to Paris and report on the position of the patents and property there, and on the steps to be taken to enforce their claims. Mr. Campbell had an intimate knowledge of French law, and was thoroughly acquainted with the French language. A meeting could afterwards be called to hear Mr. Campbell's report.

Mr. CAMPBELL, referring to a remark which had been made, stated that the shareholders need not be afraid of any liability. There were no debts, and it was a question of common action to see what could be got back for the benefit of the shareholders.

Mr. CANNING stated that the commercial liabilities were very small—about £600 or £700. There was the question of liability under the agreement, however.

Mr. CAMPBELL, in reply to other questions, stated that the liability of the Company in respect of debentures of the French Electrical Storage Company was for the interest only, and not for the principal. The amount of debentures was small he believed.

Mr. CANNING: The debentures were to be drawn over a period of twenty years.

Mr. CAMPBELL (continuing), in further reply, stated that he prepared the debentures, but what was done with them afterwards he could not say. He prepared the debentures for the directors of the Faure Company, of which M. Philippart was chairman.

A SHAREHOLDER asked whether the shareholders were liable for agreements made by the directors if they had not been ratified by the shareholders.

Mr. CAMPBELL replied that it depended on whether the agreements were within the four corners of the Articles of Association of the Company, and did not require ratification. In that case they would be good, but if they required ratification by the shareholders, and had not received such sanction, the shareholders would not be liable.

A SHAREHOLDER observed that when he seconded the resolution in December, 1882, nothing was said to the effect that their patents would be forfeited unless £30,000 were paid to the Electrical Power Storage Company. By the report of that company issued on the previous day he saw that that was the result.

A SHAREHOLDER quoted the passage referred to from the accounts of the Electrical Power Storage Company as follows:—"The French company having failed to make the requisite payment this contract is at an end, but under its terms the Electrical Power Storage Company (Limited) retains what has been received and the patents." He, however, assumed that that was one of the points which the committee would have to contest very strongly. He had read the agreement through, and with the small amount of legal knowledge he possessed it was his belief that they would get the patents back.

The CHAIRMAN, in reply to a question, said that if the appointment of the committee was confirmed, they would have power to do anything in connection with the affairs of the Company. He moved the confirmation of the appointment of the committee.

A SHAREHOLDER seconded the motion, which

The CHAIRMAN put to the meeting, and declared carried unanimously.

The proceedings then terminated.

## THE ELECTRICAL POWER STORAGE COMPANY (LIMITED).

Report of the directors to be presented to the shareholders at the annual general meeting to be held on Wednesday, the 23rd April, 1884, at the City Terminus Hotel, Cannon-street, E.C., at 12 o'clock noon.

The directors, in submitting the accompanying statement of accounts and balance-sheet up to the 31st December, 1883, have to make the following report:—The capital of the Company, which last year stood at £599,000, is changed in two respects:—1st—35,100 shares have been surrendered as part of the arrangement with the French Electrical Power Storage Company; and 2nd—the sum of £1,000 appearing in the last balance-sheet as calls unpaid has been received. The total issued share capital now stands, therefore, at £529,800, in 265,900 fully paid-up shares of £2 each. The belief expressed last year by the directors in the security and comprehensiveness of the patents possessed by the Company is confirmed by the fact that it is virtually without a rival as an electrical accumulator manufacturer. The official report of the tests made under the authority of the Imperial Commission of the Vienna Exhibition, which has been looked forward to with much interest, is not yet published, but it is gratifying to be able to state that the highest claims made as to the efficiency of the accumulators are known to have been fully established. The impediments thrown in the way of the progress of electric lighting have acted most prejudicially to the interests involved, and have necessarily affected this Company in a marked degree. The extensive demands which were reasonably to be anticipated, consequent on the expected rapid development of electric lighting, have not been realised on the scale for which the Company made preparations at their Millwall works, but the premises and plant have been maintained in a thorough state of efficiency

Digitized by Google

and repair, and are suitable for carrying out and executing with all necessary rapidity the large business which must come with the inevitable progress of electric lighting. The amount of stock and materials has been again estimated at the actual present value, viz., £18,417 5s. 7d., the heavy fall in the market value of lead alone causing a large depreciation. The loss shown for the year, beyond this depreciation in the value of stock, may justly be considered as in the main incidental to the introduction and development of a new business of a peculiar and novel character, and as of a kind not likely to recur. These and other causes have necessitated the proposal for reduction of capital hereafter recommended by the directors. Certain installations have at various times been undertaken by the Company for demonstration and experiment, and the directors regret to find they have occasioned a greater expenditure than was contemplated; on the other hand the practical knowledge and experience gained are very valuable. Great attention has been paid to the production of improved forms of accumulators. The experiments made with the cone form tend to show that for certain purposes it possesses advantages, and the new clamp cell designed by Mr. J. S. Sellon promises very satisfactory results. The competition amongst electrical companies has been so keen that some of them have knowingly accepted contracts entailing considerable loss for the sake of advertisement. When, therefore, the periods arrived for renewal of contracts for work engaged in by this Company, when a reasonable profit might have been obtained, this unwholesome competition interfered, and the directors being unwilling to undertake any permanent work which would not yield a fair profit, determined not to renew any contracts under which this was not assured, considering the advantage and value of accumulators for electric light installations to have been fully demonstrated. The largest of these, viz., at the Grand Hotel, has been most successful in this respect, and the proprietors, Messrs. Gordon and Co., have written to the Company, stating "that the light given and general arrangements were entirely to their satisfaction;" and that "bearing in mind the motive power at the disposal of the Company, it would have been impossible successfully to have carried on the electric lighting at the Grand Hotel without accumulators." From the nature of such contracts it is of course impossible to realise at their termination the whole cost of the installation, and a considerable sacrifice is therefore involved by this abandonment. The directors refer with much satisfaction to the installation made by the Company at the Bank of England, and also to the successful employment of accumulators in London, at the Gaiety and Prince's Theatres, Eberle's Army and Navy Hotel, Messrs. Antony Gibbs and Son's offices, Lord Randolph Churchill's residence; in Liverpool, at the Grand Hotel and Eberle's Restaurant; and in Parkeston, at the Great Eastern Railway Company's Station, besides other important installations. A profitable business is also arising in the temporary supply of electric light for ball rooms and private mansions, a number of such installations having been recently carried out. Reference was made in the last report to the amount received by sales of patents to the Indian and Oriental Electrical Storage and Works Company. In consequence of representations made to them the directors have concurred in the reduction of the share capital of that company, and the nominal amount of shares held therein will be therefore reduced from £50,000 to £35,000. During 1883 £5,000 in cash was received from that company, and since then a further sum of £5,000, being the balance of the cash payable. With regard to the French business the directors are at this moment compelled to observe a great degree of reticence, as in consequence of complications which have arisen the Company is now acting in the matter under legal advice both in England and France. During 1883 Mr. J. Irving Courtenay has been in America in charge of the Company's interests. The proceedings and negotiations there have necessitated a heavy outlay, from which, however, the directors are advised the shareholders may confidently expect a good return. The directors much regret, however, to have to announce to the shareholders that the sanguine hopes entertained at the commencement of the year have not been fulfilled. As the shareholders are aware the business of the Company is twofold; first, the industrial or manufacturing branch, and, secondly, the dealing with foreign patents. The depression in electric lighting has been so unexpected and prolonged that this Company, being of necessity mainly dependent upon others for its business, has suffered with more than proportionate severity in the former, while as regards the latter the high estimated value of electrical patents entertained at one time has not been maintained, and for the present there is a great depreciation in the value of such property. It is impossible, therefore, to say what realisable value attaches to the Company's foreign patents now, although the patents themselves are still as perfect as ever. After most careful consideration your directors have come to the conclusion that with the present large issued capital of the Company (£529,800) it cannot be anticipated that the industrial business alone will yield a distributable profit, but they believe that a successful manufacturing business can be profitably carried on, and show good returns on a smaller capital. They therefore recommend that the issued capital of the Company shall be reduced by £397,350, that sum representing what they consider to be at the present time the amount of unavailable assets and of loss which should be written off, thus reducing the issued amount to £132,450. The adoption of this course will not in their opinion injure the ultimate value of the patents, and will enable the shareholders more speedily to divide any profits made in manufacturing. Special resolutions prepared by counsel to effect this in the most convenient manner will be submitted to the meeting. According to the provisions of the Articles of Association, three of the directors, Sir Daniel Cooper, Bart., Mr. Frederick Green, and Colonel Steuart retire, and being eligible offer themselves for re-election. Mr. W. M. Bullivant and Mr. E. Volckmar have resigned their seats at the Board, and the vacancies thus occasioned have not as yet been filled up. The auditors also retire, and Messrs. Deloitte, Dever, Griffiths, and Co. offer themselves for re-election.

## THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).

Report and accounts of the directors for the half year ended 31st December, 1883, to be submitted to the twenty-first ordinary general meeting, 23rd April, 1884.

The directors submit the annexed accounts and balance-sheet for the half year ended 31st December, 1883. The revenue for this period amounted to £50,443 0s. 9d., and the working expenses to £12,227 3s. 2d. After providing £406 5s. for income tax, there remains a balance of £37,809 12s. 7d.; to this is added £19,434 4s. 8d., brought forward from 30th June last, making a total of £57,243 17s. 3d. First and second interim dividends amounting to £39,000 have been paid, and £18,000 transferred to the reserve fund, leaving the sum of £243 17s. 3d. to be carried to the next account. The break in the St. Vincent-Pernambuco cable, referred to at the last meeting, was repaired on the 4th December, 1883, by the ss. "Scotia." The cable recovered was found to be in excellent condition. A second interruption occurred in the same section on the 2nd March last, which was repaired on the 28th of that month. The second section of the duplicate lines has been successfully laid between Madeira and St. Vincent, according to the terms of the contract with the Telegraph Construction and Maintenance Company. The expedition with the cable for the St. Vincent-Pernambuco section will sail about the end of June, and it is expected the duplication of this Company's entire system will be completed by the middle of July next. All the Company's cables are now in good working order.

## THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY, LIMITED.

NOTICE IS HEREBY GIVEN, that the TWENTY-FIRST ORDINARY GENERAL MEETING of the Brazilian Submarine Telegraph Company, Limited, will be held at the Cannon-street Hotel, London, E.C., on WEDNESDAY, the 23rd day of April, 1884, at 12 o'clock noon, to receive a Report and Accounts from the Directors.

By order,
RICHARD COLLETT, Secretary.

8, Great Winchester-street, London,
10th April, 1884.

## NOTES.

BRITISH GUIANA.—The cable between Trinidad and Demerara is interrupted.

TELEGRAMS FOR SOUTH AMERICA.—The cable between Lima and Mollendo is repaired.

BOOK RECEIVED.—"Work-measuring Machines," by F. J. Smith. Published by E. and F. N. Spon, Charing Cross, S.W.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 11th April amounted to £3,348.

FLAME AND OXIDATION.—On Thursday last Professor Dewar, F.R.S., began a course of seven lectures on this subject at the Royal Institution.

SOUTH AFRICAN TELEGRAPHS.—The revenue of the Cape Colony from telegraphs in February last amounted to £3,903, against £3,986 in February, 1883, being a decrease of £83.

BURY ST. EDMUNDS.—A Bill has been issued to confirm the provisional order made by the Board of Trade under the Electric Lighting Act, 1882, relating to Bury St. Edmunds.

ELECTRIC LIGHTING IN PARIS.—The Société Edison in Paris have fitted up 300 Edison 16 candle-power lamps in the Opera House at Paris. A 50 horse-power gas-engine supplies the motive power.

PRIVATE BILL IN PARLIAMENT.—The India Rubber, Gutta Percha, and Telegraph Works Company's Bill came before Lord Redesdale, chairman of the Lords Committee on Unopposed Bills, on Tuesday, and was passed.

INDIAN TELEGRAPHS.—The net revenue of the Indian Telegraph Department last year was 8,17,797r., which shows that the reduction in the tariff has proved a benefit instead of a loss, as some people predicted.—*Colonies and India.*

CORK EXHIBITION.—Messrs. Emmerson, Murgatroyd and Co., Stockport, have received from the Cork Exhibition a bronze medal and award for the improved Gramme dynamo of the "A A" type, designed by Mr. Charles, their electrician.

EARTHQUAKE IN NEW SOUTH WALES.—A smart shock of earthquake was felt at Braidwood, New South Wales, on February 28, accompanied by a loud rumbling noise, apparently from north-west to south-east. The weather was threatening heavy rain at the time, but it cleared almost immediately.

QUERY.—Can any reader give the original reference to the statement that electric attraction was first discovered by a glazier, who, cleaning some window-sashes lying on a table, observed the small particles of whiting underneath to jump up and down, though the cause was not known to be electrical till long afterwards?

ELECTRIC LIGHT AT READING.—Messrs. Thomas and Taylor, the celebrated laundry engineers, have recently had a 50-light compound Gramme dynamo installed at the Caversham Laundry, Reading. The work has been carried out by Messrs. Emmerson, Murgatroyd and Co., and is a complete success. There being no gas on the premises the works are solely dependent on the electric light.

OVERHEAD WIRES.—A usually well-informed provincial paper says:—"It is understood that the Government have decided, on the re-assembling of Parliament, to ask for the appointment of a Select Committee of the House of Commons to examine into and report upon the whole subject of overhead telegraph and telephone wires. It is believed that this step has been taken at the instance of the Post Office authorities."

THE WORLD'S EXHIBITION.—This exhibition, now being organised at New Orleans, U.S.A., promises to be a "big thing." Already 900,000 square feet of the available space have been applied for by intending exhibitors. This has so far exceeded the estimates of the promoters of the exhibition that they have resolved to increase the dimensions of the main building to 1,400,000 square feet. Electric lighting and electrical appliances will be prominent amongst the exhibits.

LIVERPOOL ELECTRIC SUPPLY COMPANY.—This company have recently erected new premises in Rose-street, Elliot-street, Liverpool, which, in addition to being a manufactory, forms a central station for the supply of electricity for lighting and other pnrposes in the immediate neighbourhood. The engineers in charge of the company's works are Messrs. Holmes and Vaudrey, who have already carried out several successful installations for them, as mentioned from time to time in these columns.

ELECTRIC LIGHTING ON SHIPS.—The "Chen Yuen," an ironclad lately built in Germany for the Chinese Government, went for a trial trip not long since, during which her guns and the elaborate machinery for working them were tried with the most satisfactory results. The ship is lighted throughout with incandescent lamps on the Edison system, and these were kept alight during the time the guns were fired without suffering any damage. The installation was carried out by the German Edison Company.

REALLY NEW.—Whenever we require amusing information relating to electrical matters we turn to the daily papers. The *Globe* tells us that the seventy-five Gülcher lamps at the Crystal Palace are supplied by *three condensers*, worked by a Galloway high pressure engine. We understand the use of condensers in the laboratory for cable and other similar work, but really this is a new departure in electric lighting. Perhaps, however, condensers is an error for conductors or circuits, and a sentence referring to dynamos is left out.

SIXPENNY TELEGRAMS.—In the House of Commons on Tuesday, Mr. Fawcett stated, in reply to Dr. Cameron, that the number of telegraph messages sent last year was 32,732,000, being an increase over the previous year of 640,000, which again was an increase over the preceding year of 746,000. In reply to another question, he stated that £180,000 had been expended in the last financial year for the new works to carry out the contemplated reduction of charges for inland telegrams. No increase of the permanent staff had taken place in consequence of the intended reduction.

PORTSMOUTH DOCKYARD.—The Anglo-American Brush Electric Light Corporation have for some time past loaned to the Portsmouth Dockyard authorities one of their $D_2$ size Victoria compound wound dynamos. The authorities have, after conducting exhaustive trials with the machine, purchased it for fixing up on board H.M. gunboat "Dolphin," where it will be employed for running a search lamp of 25,000 candle-power nominal, or for lighting 100 20 candle-power incandescence lamps in different parts of the boat. The engine used will be a Brotherhood of the most recent type.

ELECTRIC LIGHTING AT CHESTERFIELD.—The Hammond Company's contract with the Chesterfield Corporation expires on May 5, and as the Hammond Company have intimated to the corporation that they require the plant for use elsewhere,

Digitized by Google

the contract has not been renewed; but the following resolution was passed at the last town council meeting:—"Resolved, that a vote of confidence be recorded in Mr. Robert Hammond and the Hammond Electric Lighting and Power Supply Company for the efficient manner in which they have conducted their business under their contract with the corporation."

CONDUCTORS.—Mr. E. J. Cowling Welch, C.E., has compiled a table giving the relative weights and sizes of insulated copper conductors for conveying currents from 1 to 2,741 amperes and the E.M.F. absorbed in each case, as well as the gauge of the wire. Thus we find that for a maximum safe current of 4 amperes the conductor (copper) should weigh 26lb. per mile. The volts absorbed per yard by the conductor will be ·0801580, and the size of the conductor will be ·04033, the nearest size of B.W.G. being No. 18. The table is published on a card in handy form for carrying in the pocket.

ELECTRICAL CONGRESS.—The adjourned congress to determine and adopt the length of a column of mercury of one square millimetre section, which represents the true ohm, meets in Paris on Monday, the 28th. M. Mascart has made some measurements which singularly agree with Lord Rayleigh's, the latter being 106·24 and the former 106·33 centimetres. England will be represented by Sir William Thomson, Professor Hughes, Professor Fleeming Jenkin, Capt. Abney, Mr. Graves, and Mr. Preece. The meeting is expected to last a week or more, for there are several other questions, including a standard of light.

ELECTRIC LIGHTING IN THE BALLET.—In the ballet at the Empire Theatre some stage "warriors," or, perhaps, we should rather say "amazons," seeing that they are of the fairer sex, carry shields and wear helmets, fitted with electric lamps which shine through pieces of coloured glass let into the shields, so as to give the appearance of jewels. The points of the spears are also fitted with an incandescent lamp. The battery which supplies the current is fitted behind the shield. It is one of the most recent forms of the Trouvé cell. The installation, if we may so term it, has been carried out by, and is under the charge of, M. Armand Levy.

SHIP LIGHTING.—The Brush Company has supplied two Victoria dynamos to Mr. Richard Miller, of Glasgow, for lighting the ss. "Mexico." The larger machine is of the type known as $E_2$, and is intended for running 250 20 candle-power lamps at a speed of 550 revs. The night or "police" circuit, consisting of about 100 lamps, which will be in use when the majority of the lamps are extinguished, will be worked by the smaller $D_2$ size machine. Both the machines will be driven by means of engines constructed by Messrs. Napier and Sons, of Glasgow, of the vertical type, and will drive the dynamos direct. This arrangement causes the floor space occupied by the dynamos and engines to be economised, a most important matter in ship lighting where space is so limited.

DOMESTIC LIGHTING.—The Rev. T. P. Johnston, of Carnbee, in Fife, has for several months past used incandescent lamps for lighting his study. The current is supplied from a bichromate battery, and is turned on by means of a switch fitted close to the door, so that a servant showing a visitor into the study can by a turn of the switch light the lamps. The switch is rendered visible in the dark by being coated with luminous paint. The lamps are of the Woodhouse and Rawson type. Though costly when used continuously, this mode of lighting is found to have its advantages. We wonder how many of the Rev. Johnston's parishioners have taken to calling on him after dark during the last few months, and how far their visits related to parish matters as distinct from the electric light.

ORIENTAL TELEPHONE COMPANY.—The report of the Oriental Telephone Company (Limited) for the year 1883 states that there has been a large increase in subscribers, but that the gain in revenue will be chiefly seen during 1884. The company has been awarded by the International Indemnity Commission 200,000f.—£8,000—on account of the losses sustained during the Alexandria riots. In India slower progress has been made than was expected, but the causes which impeded operations have been in great part removed. The directors have from the Suspense Profit Account, resulting from the conversion of the Egyptian business, transferred £10,000 to credit of profit and loss, and after distributing the dividend of 5 per cent. recently announced a balance of £27 1s. 8d. will be carried forward.

THE OPENING OF THE LEEDS MUNICIPAL BUILDINGS.—The ceremony of the formal opening of these fine buildings was enhanced by a good display of the electric light. The installation was carried out in a manner which redounds to the credit of the firm which undertook this work at a short notice and in spite of the permanent lighting having been given to another firm. The contractors for the permanent lighting were unable to be ready for the opening ceremony, and twenty-four hours before the time of opening Messrs. Crompton and Co. were asked to fill the gap. The work was successfully carried out, and a cordial vote of thanks given to Mr. Crompton, who not only carried out the work but gave it freely as a personal contribution to the expenses of the ceremony. It is seldom that a rival firm acts in so magnanimous a manner and with so wide a view to the interests of electric lighting.

ELECTRIC LIGHTING IN CHELSEA.—At the last meeting of the Chelsea Vestry, Mr. Mossop, the Chairman of the Lighting Committee, called attention to the fact that the Metropolitan Brush Electric Lighting Company had not carried out the terms of the agreement under which the provisional order in the case of Chelsea was obtained. The company had not set aside £20,000 as required, or deposited £2,000. Under the circumstances he would move that the committee have instructions to take the necessary steps for the rescindment of the order. The motion was carried, as well as one that the clerk should write to the Board of Trade on the subject of obtaining a rescindment of the provisional order on the ground that the company had broken its agreement and failed to carry it out. It was stated at the meeting that the object of these proceedings is to enable the vestry to come to terms with any other company, should they be so advised.

TELEGRAPHIC AND TELEPHONIC COMMUNICATION.—This subject was discussed at the last annual meeting of the Edinburgh Chamber of Commerce, held a few days since. Mr. Harris criticised the action of the Government in regard to telephones, and expressed the opinion that the monopoly assumed by them was antagonistic to telephonic extension.—Mr. F. Faithfull Begg referred to the recent answer of the Postmaster-General in the House of Commons as to the cost of underground communication between London and Scotland, the text of which was given in a recent note in these columns. Mr. Begg hardly thought the answer met the case, and pointed out that though the German Government had been put to great expense in laying their wires underground, the expense of maintenance since they had been so laid had been *nil*. He stated that in the Edinburgh Stock Exchange a careful note was being kept of all interruptions occurring on the wires be-

Digitized by Google

tween London and Edinburgh, and the time lost in consequence.

A "B" FOR AN "S."—A telegram to a London paper gives the pith of another telegram sent to St. Petersburg by Colonel Prjevalsky, a celebrated Russian explorer, in which the colonel announces the progress he has made in his fourth attempt to penetrate into Thibet. The last sentence in the colonel's telegram is thus given in the paper:—"It is said that hitherto the Thibetans pray Heaven to shower down bones (?stones) on our heads." We wonder who was the ingenious operator that read "b" for "s" in the first instance. The mistake makes the otherwise prosaic telegram rather comic; or it may be there is no mistake after all, and that the query is unnecessary. Possibly the Thibetans pray that in a metaphorical sort of way the bones of their ancestors may be showered down on any intruders on their territory, much as an Englishman wishes, if he does not pray, that the house may fall about the ears of, say, a tax-collector. Any one who looks at or knows the Morse code, however, will readily understand how the omission of a dash may convert a "b" into an "s," or, conversely, how the interpolation of a dash may make a "b" of an "s."

ELECTRIC LIGHTING IN GODALMING.—We recently referred to the lighting of Godalming by Messrs. Siemens Brothers and Co., and gave some account of a meeting of the Town Council of that town, at which Mr. Alexander Siemens, on behalf of his firm, announced that he could not continue the lighting at the price then paid, unless he could get several residents to adopt the electric light, in which case he might be able to continue the lighting with profit to his firm. The meeting agreed that Mr. Siemens should canvass the town, and they accordingly adjourned for a week to enable him to do so. The result of this canvass has not been satisfactory, and accordingly the contract with Messrs. Siemens Brothers will terminate on the 1st May, and Godalming will return to its gas. The gas company have, however, been wise in their generation, and have reduced the price of gas, whilst they have also improved its quality. Whereas three years ago they charged £5 5s. for each street lamp burning five feet per hour, they have now reduced the price to £4 per lamp, and have fitted them with 6ft. burners. Godalming should, therefore, have Messrs. Siemens Brothers and Co. in grateful remembrance.

PENNY TELEPHONIC MESSAGES.—The Postmaster-General has directed that the following letter shall be addressed to Mr. John W. Batten:—"General Post Office, April 15, 1884. Sir: Sir Charles Dilke has forwarded to Mr. Fawcett your letter of the 3rd inst., asking permission to try the experiment of penny telelogues or messages from one part of London to another, say from Cheapside to Charing Cross. Mr. Fawcett presumes that what you propose is to open offices at Cheapside and Charing Cross, to connect those offices by wire either direct or through the Telephone Exchange, and to permit any member of the public to send from either office by telephone a message which is to be written down in shorthand at the receiving office, and then delivered by messenger; the message, however, instead of being delivered in an envelope, as in the case of an ordinary telegraph message, to be simply read out to the addressee by the delivering messenger. If Mr. Fawcett has correctly apprehended your proposal, he is unable to see that it differs essentially from the ordinary system of telegraphing; and messages transmitted in this manner would be telegrams within the meaning of the Telegraph Acts. Such being the case, it would be illegal to charge for such messages at a lower rate than that fixed by the Telegraph Acts; and therefore, without in any way discussing the merits of your suggestion or examining the figures you have submitted to Sir Charles Dilke, Mr. Fawcett regrets that he is unable to assent to your application.—I am, Sir, your obedient servant, C. H. B. Patey."

EARTHQUAKE IN ENGLAND.—A smart shock of earthquake was felt on Tuesday morning in parts of Essex, Suffolk, and in London, especially along the Strand, Fleet-street, and Cheapside. In one large establishment on the south side of the Strand the walls actually rocked, and much alarm was felt among the *employés*, who rushed into the street. This was at 9:15. At the *Lancet* office, at the corner of Bedford-street, the compositors were startled by the sudden shaking of their frames. On ascertaining from each other that no one had been playing a practical joke they became alarmed, and fearing that the building was giving way left their work and refused to return. In London the shock was also felt at Shadwell, Wapping, and Hampstead. But in the Eastern Counties the effects were most severely felt, Colchester and neighbouring villages being partially wrecked. Here, chimney stacks came down in sufficient number to do considerable damage, whilst the spire of a congregational church in Lion-walk, 150 feet in height, was broken off. The usual rumbling sound which accompanies an earthquake was distinctly heard in this district. Ipswich, Chelmsford, Brightlingsea, Maldon, Bury St. Edmunds, Southend, and Purfleet all appear to have been visited by the wave with considerable violence. At Bury St. Edmunds the wave is reported to have passed from south to north. All the reports as to the time at which the shock occurred agree to within a few minutes. At Colchester clocks are stated to have stopped at 9:20, and that is the time at which the shock is said to have occurred at Chelmsford. Three accounts from Ipswich make the time 9:15, 9:16, and 9:18 respectively. The weather was similar to that we have been experiencing for some days past, viz., fine, with a cold N.E. wind. On none of the land or submarine lines belonging to the Postal Telegraph Service was any disturbance whatever noticed; but at Greenwich Observatory the south current needles showed a disturbance, fixing the time of the earthquake at 9:20 a.m. The horizontal and vertical force magnets were not disturbed. At the Kew Observatory also the magnetographs recorded the shock at 9h. 17-18min. Greenwich mean time, the movement indicated being north and south.

ELECTRICITY UBIQUITOUS.—Owing principally to the ignorance of writers in the newspapers, to the artificial system of education imposed upon elementary schoolmasters by the existing system, and also perhaps to the rate at which men live, the universality of electric phenomena is but little understood. The servant brushing a coat, cleaning windows, beating a carpet, placing a kettle on the fire to boil, sifting cinders, &c.; the carpenter using his plane or brush; the schoolboy or girl rubbing out the lines in his or her book; the master making or mending his pen is, during the time he or she is so employed, as effectually an electrical machine as the most elaborate apparatus made by the art of Elliot or Holtz. Many manufacturers find "electricity" a nuisance. In the weaving of various fabrics, such for example as those in which silk and wool are used, the work is very electrical. Mr. E. Bright's paper before the Society of Telegraph Engineers will give full details of the troubles arising in weaving and the methods of overcoming the difficulties. In making chocolate, sealing wax, in the manufacture of glass, in the grinding of coffee, and so on, care has to be exercised, or instead of the pure article we should obtain one highly charged with dust, not useable, and therefore unsaleable. Even the glamour of the action of elec-

Digitized by Google

tricity must be taken into our corn mills, for electricity is one of the principal causes assisting to make the miller white. When we brush our hair, or walk over the carpet, we are generators of electricity. In fact, it would seem that the greater portion of the work of the world is done in rendering electrical phenomena cognisant to our senses. Friction is largely or wholly an electrical phenomena. It must not be supposed that electricity is always in the way. The gilders, if they only knew, could tell a different tale, for their work is ofttimes aided by electricity, as is that of various workers with paper and so on. Electricity is as universal as gravitation.

THE ELECTRIC LIGHT IN SYDNEY.—The *Sydney Evening News*, of March 1st, says:—"As we have already stated, the lighting of the General Post Office by means of electricity has proved a great success. The time has now gone by, perhaps, for talking about 'experiments' in connection with this comparatively new method of illumination. Its success may be said to have been already established beyond doubt, although as with everything else further developments and greater improvements will no doubt be made in the course of time. When first the light was started at the Post Office, under the direction of Mr. E. C. Cracknell, superintendent of telegraphs, no hitch of any kind whatever occurred, and on Thursday night, by which time all the lamps were fixed, the effect was pronounced to be a complete success. Mr. H. H. Kingsbury, the agent for Edison's Electric Light Company, therefore formally handed over the paraphernalia to the authorities. While on the subject it may be well to state that an erroneous impression appears to prevail in reference to this system of lighting. Many people are under the impression that the advantage of coolness in the electric light must necessarily be accompanied by an awful glare, rendering every object ghastly in the extreme; but this is so little the truth that, in the public interest, it may be well to explain that Mr. Edison, when inventing his system, started on the basis of making the candle-power of his lamps as near that of ordinary gas burners as possible. The result is that his lamps range from eight to 100 candles, and the light may be varied according to necessity or taste. While gas must ever find a vast field for occupation, it may be hazarded that, so far as lighting is concerned, in a climate such as this it will not be many years before it will be replaced by electricity, the light from which, as supplied by Edison's Company, is at once beautifully mellow and soft." The Sydney *Daily Telegraph* of the 29th February, referring to the light, says:—"Last night the General Post Office was lit throughout with the electric light, Mr. Kingsbury, the contractor, having completed his arrangements, and formally handed over the work to the Government. The experiment, when tested last night, was a complete success, and both Mr. Cracknell, under whose general supervision the work was carried out, and Mr. Kingsbury have reason to heartily congratulate themselves upon the satisfactory result realised. In the telegraphic operating room a marked improvement strikes the observer at a glance. Here, with exactly half the nominal illuminating power of the gas that has hitherto been in use, a soft constant light is distributed, without either the heat or the consumption of oxygen which rendered the old lamps so unpleasant, particularly on hot nights. In all the other departments the improvement is equally noticeable, and the general verdict of the *employés* last night was that they were the recipients of an immense boon by the introduction of the new system.' With reference to the remarks of the *Evening News* as to the "ghastly glare" and the "candle-power," we must say that the subject is not understood by the writer in the *News*. A fourteen candle-power lamp may have the "glare" that is disliked, as well as the "arc lamps" of two or ten thousand candle-power.

ELECTRICITY, ITS EFFECT ON VITAL POWER.—A correspondent writes to the *Scientific American* as follows:—"In your paper of March 15 is an article on 'Beer Soured by Thunder,' taken from the *Brewers' Gazette*. The writer advances the idea, following the paper of Mr. Allen before the Royal Society at Edinburgh, that it might be (the souring) because of 'the electrical conditions leading to the deposition of a greater number of bacteria in a given time. This explanation would apply to beer exposed to the air in open vessels, but scarcely to beer in casks, which is practically protected from the atmosphere.' Now this matter is well worth our study, in the light to which the title we have written above directs us. We recognise fermentation as a biogenic act, and that the chemical changes produced by it are due to vital power. We have 'beer soured by thunder' because of electrical action on vital power, and no better point can be found for initiating an investigation of this action than this very point where the electrical power is brought to bear on vital power of the lowest and most simple rank. The article quoted says, 'it has been somewhat difficult to reconcile the modern theory of fermentation by germ' with the souring of beer by thunderstorms, and goes on to refer favourably to Liebig's theory of catalytic action; but properly considered we shall find that the biogenic action of electricity gives us a much easier explanation than any other. Of the almost infinite richness in numbers of the micro-organisms which in their various forms we group under the general name bacteria swarm in the atmosphere it appears probable that even our imaginations can scarcely get an idea. At all events, we know that the very slightest exposure to the air, the admission for instance of merely a tiny bubble, is sure to supply them to any fluid where we seek their presence, and it is therefore perfectly sure that a vegetable infusion like beer must be fully stocked with them at any moment, and if there comes a cause to give them a sudden and urgent impulse of vitality there will come an overpowering growth in their numbers, and we shall call it a fermentation. If it is beer at the right stage this will be an acetous fermentation, and the beer will turn sour. This has been done not by 'leading to the deposition of a greater number of bacteria' from the atmosphere, but by hastening the maturity of development of the myriads of spores which were already present. And taking this view we see readily that we have no trouble in setting aside the difficulty suggested as to the fact of beer which is in casks becoming sour almost as quickly as that which is open to the air. Why should it not be so? The spores are present in the one as fully perhaps as in the other, and the electrical condition of the atmosphere can probably act as freely on the beer inside the cask as though the cask were not there. The manner in which the difference of electrical tension chemically affects the beer at all is as yet a mystery to us, and the fact that the air rests upon its surface seems little likely to have much to do with it. A thin plate of iron is opaque to the rays or vibrations of light, but it is transparent to those of heat, presenting scarcely any resistance to their free passage and action. In the same manner the rays of vibrations of electrical energy may find the wood of the cask *transparent* for their passage. The question then arises, Are there any facts which give us reason to believe that the effects of electricity on vital power can be such as to develop fermentation?"

## ELECTRO-CHEMISTRY.—INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 535.)

**Electrolysis of Chloride of Cobalt.**—$Co.Cl_2$. Molecular weight = 130. Magnesium decomposes a solution of cobalt chloride, with evolution of hydrogen and separation of a green salt containing cobalt oxide (S. Kern, *Jour. Chem. Soc.*, 1876, Part 1, p. 880). Copper immersed in a solution of the double chloride of cobalt and sodium acquires a coating of cobalt (Becquerel, *The Chemist*, Vol. V., p. 408).

In a solution composed of 20 parts of sal ammoniac, 40 of chloride of cobalt, 20 of aqueous ammonia, and 100 of water, a brilliant deposit of metallic cobalt was produced upon a cathode of brass or copper, by means of a current from two Bunsen's cells (M. R. Boettger, *Chem. News*, Vol. XXXV., p. 166, also *Jour. Chem. Soc.*, 1877, Part 2, p. 375). To deposit the metal, dissolve five ounces of its dry chloride in a gallon of distilled water, and make the solution slightly alkaline by means of aqueous ammonia. Pass a current from three to five Smee's cells through the solution by means of an anode of cobalt (*Telegraphic Journal*, Vol. II., p. 246). By means of a separate current, an anode of cobalt, and a concentrated solution of the chloride, with its excess of acid neutralised by caustic ammonia, Becquerel obtained deposits of the metal, brilliant, white, hard, and brittle, and possessing magnetic polarity. He observed that part of the chlorine of the solution was set free during the electrolysis, and that if the liquid contained iron the greater portion of it was not deposited with the cobalt (*Chem. News*, Vol. VI., p. 126).

**Electrolysis of Sulphate of Cobalt.**—$Co.SO_4$. Molecular weight = 155. Magnesium slowly deposits hydrated oxide of cobalt from a solution of the sulphate (Commaille, *Chem. News*, Vol. XIV., p. 188).

By means of a separate current, cobalt is completely precipitated in the metallic state from an aqueous solution of double sulphate of cobalt and ammonium, if free ammonia is present (H. Fresenius and F. Bergmann, *Chem. News*, Vol. XLII., p. 75). Gaiffe deposited hard tenacious cobalt of good colour from an aqueous solution of the double sulphate of cobalt and ammonium by means of a separate current. (*Chem. News*, Vol. XL., p. 23.)

**Electrolytic Analysis of Compounds of Cobalt.**—See *Chem. News*, Vol. XLI., p. 25; Vol. XLII., p. 75; Vol. XLVI., p. 105; *Jour. Chem. Soc.*, 1877, Part 1, p. 341; 1877, Part 2, p. 925; Vol. XXXVI., 1879, p. 588; Vol. XXXVIII., pp. 284, 583, and 751; Vol. XL., 1881, p. 1,081; Vol. XLII., 1882, pp. 896, 1,320.

**Separation of Iron.**—Fe. Electro-chemical equivalent $\frac{56}{2} = 28$. A dyad cation. From slightly acidified solutions of ferrous and ferric salts, magnesium deposits iron and hydrogen gas (Roussin, *Chem. News*, Vol. XIV., p. 27). Iron in contact with gold, in acid or neutral, cold or hot solutions of salts of iron, produces no metallic deposit (Raoult, *Jour. Chem. Soc.*, Vol. XI., p. 646). Metallic iron reduces ferric to ferrous salts at ordinary temperatures, whilst platinum has no such effect. Nevertheless, if these two metals are connected together, they reduce the ferric salt more rapidly than iron alone does, and the reduced salt forms upon the platinum also, as may be seen by mixing a little ferricyanide of potassium with the liquid (Gladstone and Tribe, *Phil. Mag.* [4], Vol. XLIX., p. 425).

By electrolysis with a separate current iron is incompletely deposited as metal from neutral solutions of ferrous salts, some ferric salt being formed. If to the neutral solution of ferrous sulphate some ammonium citrate be added containing free citric acid, and care be taken that free citric acid remains in the solution, the iron will be deposited in the metallic lustrous form. No iron is separated by electrolysis from a solution of ferrocyanide of potassium, but prussian blue appears at the cathode. From the solutions of ferrous oxide in solution of sodium thio-sulphate, all the iron is separated, chiefly as ferrous sulphide. From the fluoride of iron dissolved in a solution of sodium fluoride, metallic iron is deposited (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 284).

**Electrolysis of Ferrous Chloride.**—Fe. $Cl_2$. Molecular weight = 127. According to Aikin, iron amalgam is formed by the action of zinc amalgam on ferrous chloride; but according to Damour it cannot be produced in this way (Watts's "Dictionary of Chemistry," Vol. III., p. 888). When zinc amalgam is immersed in a solution of ferrous chloride, and a crystal of a nitrate is placed upon it, a black spot is gradually formed upon the surface of the amalgam, consisting of reduced iron, which is immediately taken up by the mercury. Chlorates and other salts do not produce it (Runge, Watts's "Dictionary of Chemistry," Vol. III., p. 891).

The aqueous solution of ferrous chloride yields by electrolysis chlorine and oxygen at the anode, and iron and hydrogen at the cathode (Watts's "Dictionary of Chemistry," Vol. III., p. 377).

**Electrolysis of Ferric Chloride.**—$Fe_2.CL_6$. Molecular weight = 325. Ferric chloride is partly reduced to ferrous chloride, partly to metallic iron, by contact with sodium amalgam and a little water; and by contact with a sufficient quantity of the amalgam it is reduced to metal, which remains as iron amalgam (Cailletet, Watts's "Dictionary of Chemistry," Vol. VI., p. 816).

With magnesium and platinum in contact with each other in a solution of ferric chloride, metallic iron is soon deposited on the platinum. The passage of a feeble current, by means of platinum electrodes through a similar solution, sets free chlorine at the anode and ferrous chloride at the cathode, but a stronger one deposits metallic iron upon the cathode. (Gladstone and Tribe, *Phil. Mag.*, 4th Series, Vol. XLIX., p. 425.)

E. Becquerel found that when sesquichloride of iron, $Fe_2.Cl_3$, was electrolysed, one atom of chlorine and $\frac{2}{3}$ atom of iron are separated for each atom of hydrogen in the voltameter (Watts's "Dictionary of Chemistry," Vol. II., p. 439). A concentrated acid solution of ferric chloride yields by electrolysis chlorine and a small quantity of oxygen at the anode, and ferrous chloride at the cathode. (Watts's "Dictionary of Chemistry, Vol. III., p. 378).

I have deposited metallic iron in a reguline state by passing a current from 15 or 20 Smee's cells through a solution of sal-ammoniac, by means of an anode of sheet iron and a cathode of copper, for some time, until sufficient iron had dissolved. M. Cailletet states that by electrolysing a solution of ferrous chloride mixed with sal-ammoniac the iron was deposited in the form of mammillary masses, brittle, brilliant, and hard enough to scratch glass, and the deposit, when plunged into water, evolved numerous bubbles of pure hydrogen. Also that one volume of the iron absorbed about 240 volumes of hydrogen, which ignited by contact with a flame and surrounded the metal with a pale colour (*Chem. News*, Vol. XXXI., p. 119, also *Jour. Chem. Soc.*, Vol. XIII., p. 425). According to R. Leng, deposited iron contains 185 times its volume of hydrogen, chiefly in the layers of metal first deposited (*Chem. News*, Vol. XXI., p. 179), and Troost and Hautefeuille say that it sometimes contains as much as 260 times its bulk. (*Chem. News*, Vol. XXXI., p. 196.)

**Electrolysis of Ferrous Sulphate.**—$Fe.SO_4$. Molecular weight = 152. Sodium amalgam decomposes a solution of ferrous sulphate, and produces an amalgam of iron (Böttger, Watts's "Dictionary of Chemistry," Vol. III., p. 887). A similar amalgam is formed by electrolysing the same solution with a cathode of mercury (Joule, *Ibid* 888). Magnesium deposits from a neutral solution of ferrous sulphate hydrated ferrous oxide; but from an acidified one it deposits metallic iron (Commaille, *Chem. News*, Vol. XIV., p. 188). According to Fischer, zinc immersed in a perfectly neutral solution of ferrous sulphate, contained in a stoppered bottle, throws down metallic iron, partly on the zinc. I have found with this solution that neither antimony, bismuth, tin, lead, iron, nickel, copper, brass, German silver, silver, gold, or platinum received a metallic deposit by simple immersion.

I have deposited firm reguline iron by means of a separate current, from a saturated aqueous solution of a mixture of

Digitized by Google

two parts of ferrous sulphate and one of sal ammoniac. Walenn deposited reguline, white, silvery-looking iron, together with much hydrogen gas, from a cold and slightly acid solution composed of one part of crystallised ferrous sulphate and five of water, by means of a current from three Smee's elements of very large surface. The addition of sulphate of ammonium increased the conducting power, and formed a very good conducting liquid (*Chem. News*, Vol. XVII., p. 170). Klein employed a solution of ferrous sulphate as pure, neutral, and concentrated as possible; also a feeble electric current. These conditions are important. The iron then obtained was as hard as tempered steel, and very brittle; but after annealing it was malleable, and might be engraved as easily as soft steel. It had a specific gravity of 8·139, and contained occluded in it 13 times its volume of hydrogen. It possessed a higher electric conductivity than any commercial iron. It did not warp when heated, but slightly expanded, and was not porous (*Chem. News*, Vol. XVIII., p. 133, and XXXI., p. 137; also *Telegraphic Journal*, Vol. II., p. 128).

All ordinary depositing solutions of ferrous salts should be protected as much as possible from contact with the atmosphere, because they oxidise; and a portion of the current subsequently passed through them is expended in deoxidising them. The oxidation is retarded by admixture of glycerine, which diminishes their diffusive power. When iron is deposited from some of these solutions, and has attained a certain thickness, brilliant scales of the metal become detached and fall to the bottom of the liquid.

**Electrolysis of Ferrate of Potassium.**—I have deposited iron from an aqueous solution of this salt, formed either by igniting peroxide of iron very strongly for some minutes with caustic potash and saltpetre and dissolving the product in water, or by making a very strong solution of caustic potash, immersing in it a large iron or steel anode, and a small copper or platinum cathode, and passing a strong current from 15 or 20 Smee's cells through it until it acquires a deep amethystine or purple colour. By that time the cathode had obtained a coating of iron, which was in the state of a dark powder if the powder was too great, but had the appearance of white cast iron (or intermediate between that and the appearance of reguline deposited zinc) when the power was sufficiently weak. The solution rapidly decomposes, becomes colourless, and deposits all its metal in the state of peroxide at the bottom of the vessel.

**Electrolysis of Ferrocyanide of Iron.**—M. R. Bœttinger dissolves 10 parts of ferrocyanide of potassium and 20 of sodio-potassic tartrate in 200 of water; then adds a solution of three parts of ferric sulphate previously dissolved in 50 parts of water, and then, with constant stirring, adds drop by drop a solution of caustic soda, until the precipitate of Prussian blue is just all redissolved. The resulting solution may be used for depositing iron upon copper. (*Chem. News*, Vol. XXXVI., p. 11.)

I have observed that an anode of iron greatly resists the passage of a current into a solution of perfectly pure potassic cyanide; and that if a current of sufficient electromotive force is employed gas is freely evolved from the iron, and a minute portion of the metal is dissolved. I have also noticed that if a very thin wire of silver or gold and one of bright iron be weighed, then the two twisted together and immersed in a solution of potassic cyanide, contained in a closed bottle, and set aside for several months, the silver or gold wire has partly or entirely dissolved, whilst the iron has lost not any or scarcely any of its weight.

For the electrolytic analysis of compounds of iron, see *Chem. News*, Vol. XXXVIII., p. 26; Vol. XLII., p. 331; Vol. XLVI., p. 105; and *Jour. Chem. Soc.*, 1877, Part I., p. 341; Vol. XXXVIII., 1880, p. 284; Vol. XL., 1881, p. 1,081; Vol. XLII., 1882, pp. 896 and 1,320.

(TO BE CONTINUED).

IN PARLIAMENT.—The Electric Lighting Provisional Order (No. 2) Bill was read a second time in the House of Commons on Wednesday.

## OLD CABLE STORIES RETOLD.—By F. C. Webb.

### THE "CALCUTTA" CALAMITY.

In 1868 the Indian Government had decided to duplicate a portion of the Persian Gulf cable by laying a cable between Jask, on the Mekran coast, and Bushire, a distance of about 500 miles. The core used was Hooper's, and this was sheathed at Mr. Henley's works, North Woolwich. The ships engaged for carrying the cable were the "Tweed" (formerly the Indian Navy paddle frigate "Punjaub") and the "Calcutta". Both were sailing ships, and the "Tweed" had been engaged on the laying of the first Persian Gulf cable. The "Calcutta" was an iron ship, formerly a screw steamer, of the Golden Fleece line. The "Calcutta" was loaded with some 273 miles of cable, weighing about 1,200 tons, and sailed from the Victoria Docks on January 28, 1869. On the 25th a lunch was given on board by the owners, at which sixty or seventy persons were present. One of the part owners was Mr. Sothern, the well-known actor, and he, Mr. Compton, and several other actors were present, as also Mr. G. A. Sala. The latter returned thanks in an amusing speech for the ladies, and finished by saying that "They double all our woes, and halve all our pleasures"—then pretending to have made a slip of the tongue, he corrected himself amidst much laughter. Mr. Sothern returned thanks for the owners, and said that when he came on board he understood that he was to return thanks for the ladies, and that being little used to speaking in public he had been in a great state of anxiety as to what he should say, and whilst the rest of the company were looking at the tanks and machinery he was constantly consulting his friend, Mr. Sala, as to whether this or that would do, and consequently all the clever things Mr. Sala had said were due to him. He also said that part of the ship belonged to him, but what part he did not know, whether it was the larboard stove or the lee scuppers, but whatever it was if he did not get as much applause as Mr. Sala he would have his part out with a hatchet.

The ship sailed from Gravesend on the 29th, with a very poor looking set of men on board as crew. She had with her, however, twelve tried and experienced cable hands and a storekeeper (Mr. Slater) as passengers, all in the employ of the Indian Government. As easterly winds prevailed the Government had her towed down to a point twenty miles S.W. of the Lizard, where the tug left her on Feb. 5. On Feb. 6, at night, under sail, she came into collision with a Prussian barque, which was sunk. On Feb. 9 we received a telegram from the storekeeper, Mr. Slater, at Penzance, saying the "Calcutta" was sinking at sea. Lieut.-Col. Champain, R.E., Director-in-Chief of the Government Indo-European Telegraph Company, one of the owners, and I went to the Admiralty and saw Admiral Dacres, who instantly telegraphed to the Commander-in-Chief at Plymouth to send out H.M.S. "Terrible," paddle steam frigate, after her, and on the 10th the "Terrible" brought the "Calcutta" into Plymouth Sound. Colonel Champain and I left by mail that night for Plymouth, and were on board the "Calcutta" on the morning of the 11th.

A more curious and sad sight as regards the sudden change in the appearance of a ship I have rarely seen. When she left the Victoria Docks she was in spic and span order. The three tanks, full of cable, were all carefully sealed over with three inch planking caulked, the machinery neatly lashed and packed on the main deck, and the magnificent saloon was in perfect order to receive the staff that were to meet her in Bombay. Now the ship was some 8ft. down by the head, the fore compartment was full of water, and the main compartment had 12ft. of water forward and about 7ft. aft. But the fore cable tank situated in this compartment was empty, the cable having been run overboard, as we shall see further on, and this had saved the ship. The foretopmast was carried away and hanging over the side, and the jibboom and part of bowsprit gone. On deck there was a mass of wreckage, and a fine steam pinnace, which was being sent out to the cable-repairing ship in the Persian Gulf, was lying askew on the deck, an attempt having been made to launch her. Down below was a more curious sight still; the deck was strewed with open chests, bibles, and other books, shirt collars, sextant

Digitized by Google

boxes, preserved meat tins, broken plates, old clothes, knives and forks, jam-pots, and every conceivable thing used in a cabin. Having to gather information as to the position of the jettisoned cable, &c., I had to take the evidence of all survivors, and the following is, as well as I can recollect, what had occurred.

The ship, in trying to put her helm hard over to avoid the collision, had carried away the wheel ropes. The collision then occurred, the barque was sunk with all her crew, and the "Calcutta" commenced to make water. The fore compartment slowly filled, and began to wash over into the main compartment. Our cablemen then began to take the covering off the fore tank, and, after much difficulty in getting the first plank out, succeeded in ripping off all the planking and taking up the cross bearers. They then rigged up two little fairlead sheaves (the same kind as those used at Henley's on the jack stays when shipping cable). One was placed over the centre of the cone, and the other made fast to the rigging over the starboard side. They rove the end of the cable through these, attached a chain and buoy, and let the end go. The ship was then drifting helplessly up Channel, as her rudder was useless. The captain, thinking the ship was about to founder, ordered off our men—they being legally passengers—in two boats. One with the storekeeper and six men fetched Penzance, and the storekeeper telegraphed to us in London. The other fetched a Greek brig. This boat had an old cable foreman named Chamberlain, who had been with me in the old "Monarch." It was he who had got the cable deck up and buoyed the end of the cable. He had also the thought directly he was on board the brig to take a bearing and estimate his distance from the Wolf Rock, and also the same of the "Calcutta," and from this information I was able to plot the position of one end of the cable. In getting on board the brig one poor fellow, an engine driver, got foul of some ropes over the stern and was drowned with his head downwards whilst hanging from the ship, and another cable hand, a fine young fellow, who was with me as a fireman on the Havanna cable when I lost so many hands from yellow fever, and where he was always one of the volunteers for burials, was also drowned. He was a strong swimmer, but for some reason they could not get to him.

In the meantime on board the "Calcutta" the captain was preparing his largest boat to leave with most of the crew. He was down below getting his chronometers, &c., together, when about thirty of the ragamuffins that I had seen at Gravesend had got into the boat, cut the painter, and with a cheer left the ship. Curiously this boat turned up at Penzance without anybody in her; she was not bottom up, but floating properly and with a file in her, which showed she had not been capsized. It was thought that the missing men had got on board some passing ship, but nothing was ever heard of them as far as I know, and if they were not drowned they pretty nearly deserved it. This left on board the captain and some thirteen officers and men, including three young midshipmen. And now comes a most painful incident as it was told me. The boats left on board were the captain's gig and a small dingy. The captain got ten men and officers into the gig whilst she hung from the davits, and saying "Good bye" to the three little midshipmen, with tears in his eyes, left them in the sinking ship to do the best they could with the dingy. But in lowering the gig the eye-bolt of the after tackle drew, and the boat, hanging by one fall, sent the captain and five of the rest into the sea, and they were all drowned. The other five scrambled on board, thus leaving eight on board. One of the midshipmen (the son of a captain in the navy) was asked by one of Lloyd's officers, an old merchant captain, what they did then. "Fired away all our powder and blue lights, sir." Well, and what then? "Oh! we went down below and had some supper," was the reply, which seemed to amuse the old salt. The eight were eventually taken off by the Cadgwith lifeboat. This left the "Calcutta" drifting up Channel a derelict. The last end of the sixty-three miles of cable in the fore tank had gone over before she passed the Lizard.

A fisherman boarded her and sent his own boat into Plymouth to give the intelligence, but was careful to get another boat to stand by him. A Falmouth tug came out and got the big derelict in tow, but parted all her hawsers, and was on her way back to Falmouth for fresh ones when she was met by H.M.S. "Terrible," the captain of which ship asked for the bearings of the "Calcutta." These were given, and when the "Terrible" came up to her they found the wide-awake fisherman pretending to steer her with the ropeless wheel to show that she was his find. A lieutenant and some 20 men were with some difficulty put on board, and the ship was towed into Plymouth. The ship was found to have a jagged hole about 2ft. diam. in her port bow close to the cutwater, but within the collision compartment. This compartment was a covered-in compartment, and only held a few tons of water, so that little harm would have occurred to the ship, but that the small hand-tap leading from this into the fore compartment proper had been left open, thus filling the fore compartment. The emptying of the fore-cable tank by jettisoning the cable, weighing some 250 tons, clearly saved the ship, and this was entirely due to our cablemen, but they got no reward for this from the underwriters, although the wide-awake fisherman got some £200.

The cable that was run out had all to pass through the two fairleads previously mentioned, and as these were only big enough to allow the cable to pass, no kink could have left the ship, which speaks well for the Newall cone principle. Had there been any telescoping arrangement, with nobody to lower it, it is pretty certain that the cable would have clung round it when the coil was low, and something would have been carried away.

I plotted down the position of the cable from the information given me by Chamberlain's bearings, and the time given when the other end went over. We went out in Henley's steamship, the old "Caroline," and grappled to get the cable a few miles from the last end paid out. We hooked the cable at first dredge at fourteen miles by cable from the end. As the sixty-three miles of cable covered only twenty-five miles of ground, from being paid out without any breaks, this was really within about three or four miles by ground of the cable end, which, considering the case, was not a bad shot. The end of the fourteen miles was buoyed, and the balance picked up to the end, about eighteen miles from Scilly. During the latter portion of this work the old "Caroline," getting beam on to the sea on the weather tide, rolled furiously. This just at dinner time. There was Captain Galilee at the head of the table, Mr. Frasi on his right, and Mr. Herbert Taylor and myself on the other side. The ship gave such a lurch that the bench Mr. Taylor and I were sitting on came up by the roots and we dropped gracefully over to leeward. At the same time Mr. Frasi clutched at the table, but Captain Galilee having a brand new carving knife in his hand tried to save the leg of mutton, and thus brought the carving knife down on Mr. Frasi's fingers, inflicting a serious cut. The cable end soon after this peculiar incident came on board.

The cable, including the other fourteen miles, was all recovered, but from its having been lying on the ground in numerous half hitches was full of kinks. They came on board at times regularly every eighth of a mile. All this cable was landed at Keyham Dockyard, the kinks cut out and splices made, some 300 in all. The cable in the main tank and after tank of the "Calcutta" had also to be landed to allow the ship to be docked. It was eventually put back in the "Calcutta," including three or four miles formed of pieces too short to splice. The expedition was detained for some months, as the season was lost, and the "Calcutta" finally sailed on June 27, with a total of 269·4 n. miles of cable, and the "Tweed," with 265·9 n. miles, left on June the 30th. During the work of splicing up this cable I made the experiment with an insulated room described in the *Philosophical Magazine*.

The staff, under Lieut.-Colonel Champain, R.E., including Mr. L. Clark, Mr. Herbert Taylor, Mr. G. Preece, and some fifteen foremen, artificers, &c., went overland to meet the ships at Bombay, and were wrecked in the P. and O. steamer "Carnatic" on an island in the Red Sea. Some thirty of the ship's crew were drowned, and after some narrow escapes the rest were for several days on a desert island—Mr. L. Clark with his collar-bone broken.

The cable was eventually successfully laid in spite of a

Digitized by Google

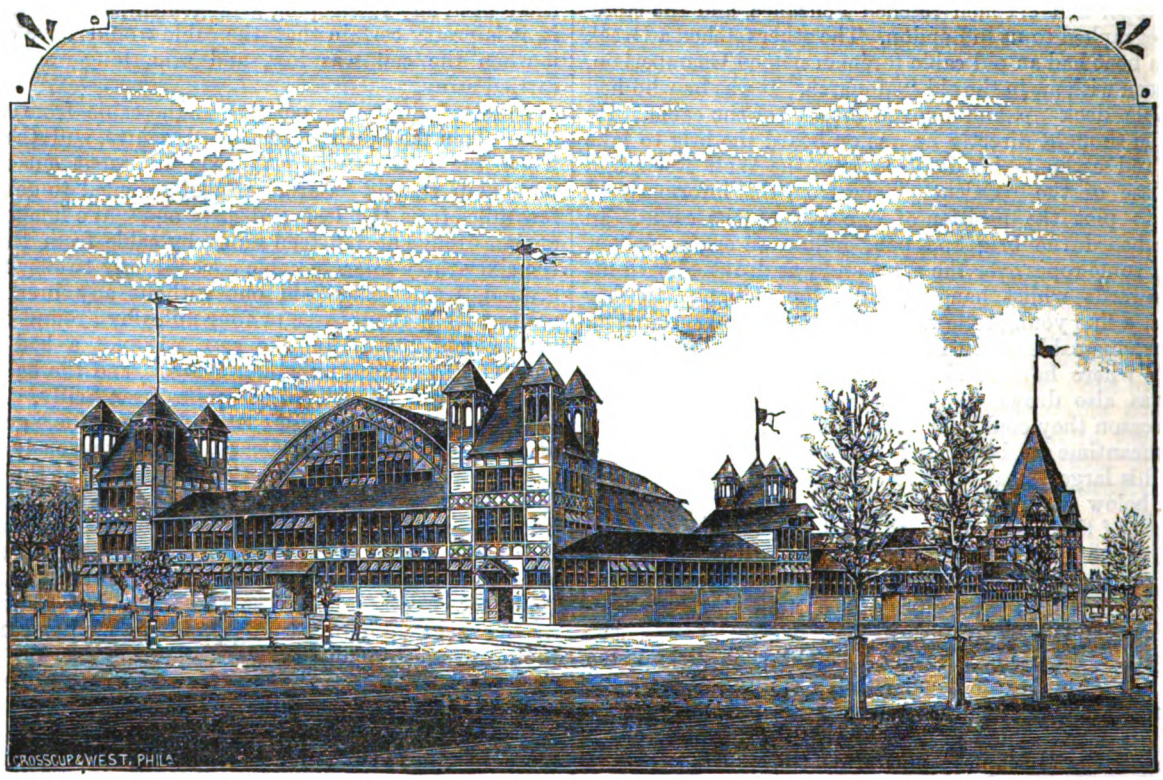
heavy gale, but a description of this would form a separate story. It is curious that the section forming the cable picked up, and which had the 300 splices in it, tested better than any of the others when the ships arrived at Bombay, that section giving 3,513 megohms per knot, the highest of the others being 1,700. All the numerous joints and pieces in the sixty-three miles had been carefully tested by Mr. Herbert Taylor, and to this may be attributed in a great measure this perfection.

The expenses caused by the accident to the "Calcutta" had to be recorded in a separate series of accounts, and to distinguish them they were kept under the heading I have given to this narrative, viz., the "'Calcutta' Calamity."

## THE FORTHCOMING EXHIBITION AT PHILADELPHIA.

The International Electrical Exhibition, to be opened in September next, under the initiative of the Franklin Institute, will join the towers. The building will have second story apartments at its ends on Thirty-second and Thirty-third streets respectively, with stairways leading up in the towers from the ground floor. The towers themselves will be three stories high. Two long and narrow hallways will afford communication between these apartments. The remainder of the ground will be enclosed by a large triangular building one story in height and joined to the main hall. The main entrance to the building will be at the corner of Thirty-second-street and Lancaster-avenue, another at Thirty-third and the avenue, and one at each of the other towers. Five exits are provided for on the plans, but desirable changes may hereafter be made in the number and situation of both entrances and exits before the work is completed.

The meeting of the American Association for the Advancement of Science, which will be held this year in Philadelphia, and the expected presence of many representatives of the British Association, which will meet this year in Montreal, will attract a numerous and influential scientific gathering in Philadelphia during the time of the holding of the exhibition; and in order that so exceptional an opportunity to promote the



The Philadelphia International Electrical Exhibition Building.

is being actively organised. A short account of the present condition of affairs is given in the April number of the *Journal* of the Institute, to which we are indebted for our information, while our good friend Mr. Johnson, the editor and publisher of the *Operator* and the *Electrical World*, has favoured us with the accompanying illustration. This gives a view of the exhibition building, now in process of erection. The building is being erected by Mr. Jacob R. Garber, from the plans of the architects, Messrs. Wilson Brothers and Co. The following brief description will give a general idea of its character:—"The main building will be rectangular, having a length on Foster-street of 283ft. and a breadth of 160ft., extending from Foster-street to Lancaster-avenue on Thirty-second-street, and part of the distance from Foster-street to Lancaster-avenue on Thirty-third-street. A tower 60ft. high will be situated at each of the four corners of this building. One central arch of 100ft. span and 200ft. in length, of the Gothic style of architecture, will cover the greater portion of the space occupied by this building, while two smaller ones, having a span of thirty feet, and running parallel to it on either side, interests of science shall not be lost, Congress has been requested to authorise the holding of a National Conference of Electricians, to convene in Philadelphia at this time. Should Congress, in its wisdom, make the proper provisions for holding such a conference, the results promise to be of much value.

The scientific character and importance of the exhibition have been appreciated by the United States Government, and an official letter issued by the Department of State, conveying instructions to the United States diplomatic officials abroad, is a flattering tribute to the reputation and usefulness of the Franklin Institute. A scheme of classification has been elaborated; a system of rules and regulations to govern the internal management of the exhibition has been adopted; provisions have been made in the interest of intending foreign exhibitors, to relieve them of all trouble in respect to the passage of their exhibits through the Custom House, and for the proper reception and care-taking of the same on their arrival; and arrangements have been made to return, free of charge, goods on which freight charges have been paid one way.

## THE MAXIM-WESTON COMPANY IN ENGLAND.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice in *The Electrician* of the 19th inst. some allusions to the United States Electric Lighting Company, to the Maxim-Weston Company, and to myself, which I feel called upon to reply to.

The purport of the article referred to is that the United States Electric Lighting Company are doing a large business in the States, and that it is a wonder that nothing is now heard of the Maxim-Weston Electric Company (English), who own the same system and patents, especially as Professor Maxim was said to have been "retained at a high salary to establish a sound business."

In answer to this I would say that it is quite true, as you assert, that the United States Electric Lighting Company are doing a very large and prosperous business in the States. We have at Newark, New Jersey, twelve miles from New York City, a large and magnificent factory, equipped with the finest machinery and tools that can be purchased; we have a large corps of the most skilful electricians and mechanics; we have in New York our offices and show rooms, large, commodious, with beautiful appointments and every device and facility to show off our system to advantage. We own all the buildings which we occupy. None but the very best mechanics are employed at our factory; in our business and sales department we have none but educated and refined gentlemen of pleasing address, and, need I say, plausible and convincing conversationalists. When we make an installation we try to have all the work so thoroughly planned and executed that we have no apologies nor explanations to make. We do not find it necessary to lie to our customers; we avoid all lawsuits, if possible; we do not light our own place with gas, but use our own lights; we have plenty of money.

We have the system, the means, and the men to succeed; the public have confidence in us, purchase our goods, pay for them, and we make money and pay good, honest dividends. This is simple, is it not? Had we reversed all this except the system, you would never have heard of us.

It is not true that I am "retained at a high salary" by the Maxim-Weston Company. The fact is, I have never received one penny from said company, notwithstanding that they have had a great deal of my time, and I have travelled about the country at my own expense attempting to assist them.

About one year ago while in Paris, Mr. Nicholas de Kabath, then one of the directors of the Maxim-Weston Company and the largest stockholder, sent for me to come to his office. He said to me, "Will you go to London for two years, go into the factory of the Maxim-Weston Company, re-organise it, put the whole thing on a sound basis, and do all you can to make the company's business a success? The home company is anxious to have the English company succeed, and the home company has agreed to pay one-half of your salary of £1,000 provided the London company will pay the other half." I told him that I would go if the home company approved of it, and I therefore telegraphed to New York. Within twenty-four hours the whole matter had been settled by telegraph and I had accepted.

Mr. Kabath said:—"The English company are out of money, but they believe that they can raise money if it were understood that you were to take charge of the factory and that you had been engaged. I have a communication from Hugh Watt, the managing director to that effect. We wish to use your name to raise money; will you allow us to do so?" I consented, and my consent was telegraphed to Watt.

You will remember that about that time it was published in the newspapers not only that I had been engaged by the English company, but also that I was one of the best, if not the best electrician in the world, and that this statement met with considerable ridicule at the time.

Mr. Kabath soon after this left Paris for London, and upon arriving he telegraphed for me to come to London at once. I did so expecting to enter upon my duties, but before doing so I wished to have some kind of a written agreement, and for this purpose I had many interviews with Watt, the managing director, and Mr. Kabath.

They had used my name and had raised £6,000, but Mr. Watt said that the finances of the company would not warrant them paying me so high a salary, namely £500 a year. (The American company had already agreed to pay me the other £500, and I was bound by my agreement with them to stay in London two years.) I then said, "If you cannot pay me the £500 a year, take any portion of my time that you like and pay me accordingly."

Mr. Watt said he would bring the matter before the Board meeting, and at Mr. Watt's suggestion they voted to give me the magnificent salary of one guinea per annum. About this time, during the temporary absence of Mr. Kabath, a measure was rushed through the Board increasing the managing director's salary to £600 a year for three years.

Having been engaged by the company, I suggested to them that they should allow me to have one of their unoccupied offices at Bankside. This was answered by the question, "How much will you give for it?" I replied in writing that I would give one-half of my salary—namely, ten shillings and sixpence per year. This communication was not noticed by them.

However, they gave me a large package of patents to examine, and wished me to make drawings of a large slow speed machine. I replied that I could not examine the papers while standing in the street, and that they would have to wait until I procured a suitable office; and, moreover, that they had already had a guinea's worth of my time.

At the next Board meeting Mr. Watt had me formally kicked out of the company's employ as the electrician and consulting engineer of the company, but as yet he has not paid me my guinea.

I would say, in conclusion, that I have agreed to stay in London two years, and that I am going to stay; that I have established myself in an experimental factory at 57D, Hatton-garden, and I invite all the stockholders of the Maxim-Weston Company and all interested parties, to first visit the factory of the Maxim-Weston Company, wherever it may be, and then to come to my little factory, see what I am doing, and observe the difference.

It should be said to Mr. Kabath's credit that when he heard of the large sum of money voted to the managing director, he at once withdrew from the Board, stating that he could not afford to be associated with any concern where such a transaction was possible.—Yours, &c.,

HIRAM S. MAXIM.

57D, Hatton-garden, E.C., April 23, 1884.

## PROFESSOR D. E. HUGHES'S THEORY OF MAGNETISM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have been much interested in the theory of magnetism which Professor D. E. Hughes has enunciated as the outcome of his experiments on bar magnets, a statement of which experiments, together with the theory, I have read in *The Electrician*.

It is not altogether uncommon for two individuals, as in the present case, to arrive at the same conclusions upon a subject, even when their investigations have been conducted by perfectly different methods, and quite distinct from one another. As, however, I find from the journals that the theory advanced by Professor Hughes is considered to have been originated by him, it appears right to point out that my experimental researches into magnetism had enabled me to formulate an almost identical theory, which I published in a series of papers in *The Electrician*, entitled "What is Electricity?"

If I interpret Professor Hughes aright, he considers magnetism, like heat, a mode of motion, and he has arrived at this conclusion from the curves of magnetic force which he has observed and examined in bars of iron and steel under different conditions; in fact, after describing the phenomena of the curves, he says: "It would be difficult to explain these effects upon any hypothesis except that of molecular rotation, for if we regard it as simply a case of magnetic induction, the stronger reacting upon the weaker,

Digitized by Google

we fail to explain the perfect spiral, *helical* (?) form of the opposing waves."* And, again: "I regard the magnetic endowed qualities of all matter or ether to be inherent, and that they are rendered evident by rotation to a symmetical arrangement in which their complete polar attractions are not satisfied."† The exact character of this motion Professor Hughes then describes as follows:—"When magnetism becomes evident the molecules or their polarities have all rotated symmetrically, producing a north pole if rotated in a given direction, and a south pole if rotated in the opposite direction."‡ And he concludes his lecture at the Royal Institution in the significant words:—"Time will not allow me to show how completely this view explains all the phenomena of electro-magnetism, diamagnetism, earth currents, in fact all the known effects of magnetism up to the original cause of the direction of the molecules of the earth. To explain the first cause of the direction of the molecules of the earth would rest altogether upon assumption as the first cause of the earth's rotation, and of all things done to the inherent qualities of the molecules themselves."§

Now if we are to consider magnetism as a mode of motion, there can be no manifestation of magnetic power without motion, and how does this accord with the views of Professor Hughes, "that when magnetism becomes evident the molecules or their polarities *have* all rotated symmetrically, producing a north pole if rotated in a given direction, and a south pole if rotated in the opposite direction." These words appear to mean that after the molecules have rotated to a given point they then become fixed in such position, and if so how can magnetism be a mode of motion? Now I quite concur with Professor Hughes that magnetism is a mode of motion, and I hope to give a satisfactory solution of the above somewhat abstruse question when I call attention to the manner in which I have stated it as my conclusion that the earth obtains its magnetic charge.

We will now turn to my investigations on the same subject. My first published observations into the character of the magnetic force were contained in a paper read at the Royal Society in 1879,‖ the title of the paper being "On a New Method of Investigating the Magnetic Lines of Force in Magnets, demonstrating the Obliquity of the Equator and Axis of Bar Magnets." The method consisted in suspending over every portion of the bar surface needle-point test magnets ranging from $\frac{1}{16}$ to $\frac{1}{4}$ of an inch in length. By such means I was enabled to show with great accuracy the curves of magnetic force, as the force was manifested over every portion of the magnets, together with the obliquity of the equator of bar magnets and other phenomena previously unknown. I continued these investigations by fixing two bar magnets lengthways in a groove, and by then placing one of the needle points on the end of the distant bar and pushing the other magnet towards it I was enabled to define the character of the motion, and to ascertain that the force emanated from the bar in the form of right and left-hand helical directions, by which the significance of Faraday's lines of magnetic force became evident. I was thus also able to show that magnetic attraction depended upon two helices of similar denomination working into each other from opposite directions, and that magnetic repulsion was the result of dissimilar helices colliding as oblique forces against each other.

It is now well known that the true magnetic pole is not situated at the end of the bar, but at some little distance removed from the end towards the equator. The *cause* of this phenomenon, by means of my observations, admitted of ready explanation, for upon placing two dissimilar poles together, which state of things is significant of magnetic attraction, the equator of each bar is removed from the centre, and is now situated at the line of junction, whereas if two similar poles, which are representative of magnetic repulsion, are brought together, the two poles vanish from their position near the ends and are replaced by a *single* pole at the line of junction, thus demonstrating that the action which proceeds from the equator of a bar magnet in either direction towards the bar ends is met by a corresponding reaction, just as in the case of the two separate bars, and that the perpendicular position of the needle at the true pole is dependent upon its being supported on all sides equally at such point. The obliquity of the equatorial line and the curved lines which passed up the bars were significant of the resistance which the bar matter offered to the passage of the force, for although these lines might vary somewhat in different bars I found from the many bars which I examined that the variation was too slight to set aside the existence of the law described.

All these phenomena and several others I exhibited at the *conversazione* of the Royal Society held on April 30, 1879. I also read a paper at the Physical Society of London on the same subject in 1879, and notices of these papers were published in *The Electrician*, *Nature*, &c., immediately afterwards.

Subsequently I endeavoured to ascertain the cause of terrestrial magnetism, and inasmuch as all artificial magnetism is the outcome of unpressed force I was led to regard this as due to the earth's motion through the lines of force unpressed upon it by the sun.

In the paper on this subject which I read at the meeting of the Physical Society on June 12, 1880, printed copies of which paper I distributed at the time, I pointed out that "the earth as a mass of matter is to be regarded also as a reservoir of energy, every form of matter entering into its composition being not only fully charged with the energy, but in direct communication with the sun by means of the continuity of the energy acting through space. In fact the earth may be compared, as far as the energy is concerned, to a lake of water, the running level of which is maintained by the streams of supply and outfall. Every vibration, therefore, which is emitted by the sun which comes in contact with the earth tends to eject a like amount of energy from the earth, a new direction and impetus having been imparted by its passage through the earth."

I further pointed out that the solar energy which impinges on the earth and develops heat, more especially in the line of the ecliptic, assumes right and left-hand helical directions as it traverses the earth towards the north and south poles, where, after undergoing many changes of state in its passage through the crust of the earth, it makes its exit again.

Now, this latent energy or *vis viva* of the earth is brought to a point at each of the magnetic poles of the earth, where it is met by a vortex of force of the opposite direction, the point of which is directed towards the magnetic pole of the earth just as occurs in artificial magnetism.

I next showed that if this be so, then the earth's rotation cannot be said to be maintained by inertia alone, unless this be the basis upon which inertia rests; but that it is partly the effect of resistance, an example of which is given in the rotation of Hiero's steam engine, and partly also of refraction which energy undergoes when it reaches the mass of the earth.

The late Professor Clerk-Maxwell arrived at the conclusion that matter was endowed with different properties owing to the mode in which the particles of a common matter, the ether, were primarily combined.

It will be seen that the theory which I have evolved from the study of magnetism entirely supports this view, and shows that the axial inclination of the earth, and every planet in the outcome of the mode in which the particular description of matter of which each is composed refracts the energy of the sun, and as the *vis viva*, or display of natural phenomena which a planet exhibits, is the outcome, other things being equal, of its particular description of motion owing to its axial inclination to the sun, so the particular manner in which the particles of matter are combined is the mechanism by which all the work is effected.

After the foregoing remarks it will not, I think, be difficult to understand, that even when the molecules "have been rotated," as Professor Hughes has described, that they may continue rotating upon the same axis without apparent motion, for the first swing of the bar under the action of impressed magnetic force would place the mass and every molecule of

* *The Electrician*, Vol. XII., p. 430. † *Idem*, p. 394. ‡ *Idem*, p. 391.
§ *Idem*, p. 394.
‖ Vide *Proceedings* of Royal Society, 1879.

Digitized by Google

the mass in such a line as to permit the force being transmitted with the least resistance. This having been accomplished, it is evident that molecular rotation could continue in the artificial steel magnet without visible motion, just as it does in the soft iron bar when such is converted into a magnet by a current of electricity in a coil of wire, only with less freedom, the only essential being the continued action of the impressed force.

Now, upon applying this principle to terrestrial magnetism and diamagnetism we perceive that the force which reaches the earth from the sun in the shape of heat or light is found to affect the whole sunward surface of the earth, and that the crust of the earth, more especially in the intertropical regions, is traversed by this force, or kinetic energy, which, starting from the line of the ecliptic, necessarily moves towards the poles with a general helical direction of a right and left hand character, as I have described. It further appears that *each variety of matter has an influence in modifying the direction of this force, and so is productive of phenomena which are peculiar to the condition of the matter*, and I would point to the evolution of *colour* and *local* manifestations of magnetic polarity as two of the most striking displays of natural phenomena arising from such cause.

Upon referring to some papers which I published in *The Electrician*, in 1881 and 1882, under the title, "What is Electricity?" I find I used these words, "I do not claim that the methods which I have adopted in my investigations are essentially new, but that the very minute test magnets I have employed to trace out the manifestations of this force in its form of magnetism over every portion of the surfaces of magnets—magnets under separate and combined action—have enabled me to divest this branch of science of all theory, and to reduce it to a system of applied mechanics;"* and, further, I show that all electric and magnetic phenomena are only different manifestations of that energy which exists in matter as an element of its constitution.

Although there is thus seen to be great similarity in the words I used about three years since, and those of Professor Hughes so recently expressed, it will be perceived that our views differ with regard to the identity of the two forms of force, as I have adduced evidence showing that they are only modifications of one and the same force, and that the two forms of force act in similar planes. This, indeed, becomes evident when we regard, as we are bound to do, the *locus* of the points at which the needle stands at right angles to the bar as the plane of force, for at these points are the resultants of all the curved lines of force on either surface of the bar; moreover, all these curved lines vary in their co-ordinates according to their situation on the bar. We therefore perceive that the plane of magnetic force is at right angles to the axis of the bar, and that the motion of the galvanometer needle is due to an effort to place the force emanating from the bar parallel with the force moving in the wire.

For the further consideration of this subject and the mode in which the energy of the sun is utilised by the earth in the maintenance of natural phenomena, not excepting animal and vegetable life, I must beg to refer to *The Electrician*, Vol. VIII., pp. 197, 233, 267, 353, and 410, and to Vol. IX., pp. 85, 110, 181, 326, 393, and 512.

By the way, I cannot perceive in what manner Professor Hughes accounts for the phenomena of magnetic attraction and repulsion by means of his curves, unless it be in the mode which I had previously pointed out; neither can I understand upon any other principle than that which I have advanced *why* the pole of a magnet is situated at some distance short of the bar end, or why, when two similar poles are placed together, the polar manifestations are removed from their usual situation and occupy the line of junction, unless the phenomenon be the outcome of that action and reaction to which I have attributed all magnetic phenomena.—Yours, &c.,

RICHARD C. SHETTLE, M.D.

73, London-street, Reading,
April 14, 1884.

## THE HEATING EFFECTS OF ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Knowing, as you and your readers do, how much time I have devoted to this subject, you will not be surprised at my wishing to make a few remarks on the letter with the above heading by Mr. J. T. Bottomley which appeared in your last issue. He shows that his experiments at low temperatures do not tally with those of Mr. Preece at high temperatures, and that Mr. Preece has accepted the law for equal heating, which gives $(\text{current})^2 \propto (\text{diameter})^3$, while his own experiments make the current more nearly proportional to the diameter, or, as he puts it, the emissivity of surface of a small wire is greater than that of the ball of 4 centimetres diameter upon which Mr. McFarlane experimented.

Now, I know Mr. Bottomley far too well to suppose for a moment that he would wittingly ignore my earlier work. Still, it is only right that I should draw attention to my results announced at the British Association in 1882, and discussed by me more fully in *The Electrician*, September, 1882; the *Annales de l'Electricité*, October, 1882; and at the last meeting of the Society of Telegraph Engineers and Electricians. I there stated the theoretical law, and announced the experimental result that the current in small wires varies more nearly as the diameter than as the diameter $\times \sqrt{\text{diameter}}$ for equal heating.

At the same meeting of the society I showed theoretically that insulation enabled a greater current to be carried without over-heating up to a certain diameter. If the diameter of cable is twice that of the conductor, this critical diameter of conductor is 4·8 centimetres. If four times it is 3·0 centimetres. If the cable be 100 times the diameter of the conductor, then if the conductor be 1·0 centimetres diameter, the heating of the conductor is the same as if there were no insulation. This is with gutta percha insulation. From what Mr. Bottomley says it appears that Sir William Thomson stated before the Royal Society of Edinburgh on March 3, 1884, that with small wires insulation favoured the current. Of course, had I been aware of this I should have referred to it in my paper before the society last month, and it is very interesting to me to find that Mr. Bottomley has experimentally confirmed the fact stated in my paper (from theoretical grounds), viz., that with equal conductors, if not large, an insulated one can carry the largest current without overheating.—Yours, &c., GEORGE FORBES.

34, Great George-street, Westminster, April 21, 1884.

## THE CAUSES OF HEATING IN THE IRON CORES OF ARMATURES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: That heating follows as a consequence of the phenomenon referred to in my letter published in your journal of the 29th ult. Mr. Mordey evidently agrees, though with the qualification that the effect is feeble. The question may, I think, be also considered from the standpoint of change of polarity; that this is continually going on in a revolving armature does not require discussion. We have the authority of Prof. Hughes, in a letter to your able contemporary, *The Engineer*, published on the 11th inst., for the statement that heat is thus produced, and is "due in great part to the frictional resistance of the elastic medium surrounding each molecule against each other." This is the opinion of the greatest authority on magnetism.

In the last number of the *Journal* of the Society of Telegraph Engineers, p. 147, the abstract of a paper in the *Beiblätter* on "Heating of Iron by Alternate Magnetisation" is published. It contains an account of some experiments which lead to a conclusion similar to the above regarding the causes of such heating. Proof is also afforded of the efficacy of slitting or dividing iron subjected to the influences above mentioned.

With Mr. Mordey, I fully recognise the difficulty of arranging experiments of a satisfactory nature; should such come to my knowledge or suggest themselves to me, it will afford me great pleasure to advise you of them for the benefit of your readers.—Yours, &c., F. H. NALDER.

Isleworth, April 22, 1884.

## EARTHQUAKES.

Any stranger who chanced to see the crowds of people gathered round the newspaper office windows last Tuesday at noon might have imagined that an invading host had unexpectedly landed on these shores. The astonishment depicted on every face at the news of an English earthquake could hardly have been greater if the intruder had been some foreign army corps. In countries accustomed to visitations of either kind such news is received with the consternation or awe which sad experience quickly inspires. But with us the case is different; we have happily no experience worth mentioning of the convulsions of nature under ground or of contending armies above it, and the result is that a rumour relating to either of these dread calamities would be received alike with simple wonderment and incredulity, but not with alarm. It has, however, long been known, or supposed, that some portion of this island is in a line, or closely adjoining the line, connecting the volcanic regions of the Mediterranean with the northern volcanic outlets in the island of Iceland. The wonder, therefore, is—supposing the connection actually to exist — that our intermediate position is not more frequently and more seriously affected by the perennial disturbances in those regions. Occasionally a brief paragraph records that some obscure neighbourhood has felt, or fancied it has felt, a slight shock; and in a certain part of Scotland—Forfarshire, we believe—these sensations are common, but always of the most trifling or dubious character; and, on the whole, it may be said that if we want to learn anything about veritable earthquakes in England we must go a long way back in history, and even there we shall not find anything to seriously disturb our insular equanimity.

This being the case, we have paid very little attention to earthquakes in general from the social, and not much from the scientific point of view. But it happens that we who possess the great majority of the world's submarine cables, and a not inconsiderable portion of its land lines connected with them, are in an excellent position to study the phenomena attending these disturbances; and if anything could reconcile us to the unpleasant and unwelcome visitor of Tuesday it would be the increased attention now likely to be given to the subject by the people most competent to study it. It is well known that both before and after these disturbances magnetic perturbations are experienced nowhere more conspicuously than at submarine cable stations; and it may be hoped that what has just now happened at home will lead to some more general and systematic observations being taken all over the world with a view to mapping out exactly the regions liable to disturbances and the tracks they usually follow. In the present condition of our knowledge it would be rash to say that anything of real service can be done towards averting a catastrophe, but something might be done by way of warning; and as one chief horror of the earthquake lies in its unexpectedness, to be forewarned would deprive the event of most of its terrors, and perhaps much of its dangers. For it should be remembered that where shocks of earthquake are most frequent their effects are least disastrous, buildings being specially constructed to meet such contingencies, and social conditions adapted to the ever recurring risks. Long immunity from serious convulsion will often lead to negligence in this respect, as at Agram and Casamicciola and elsewhere quite recently; and it is at such points especially that due warning would be of inestimable value. No warning was given; yet it is almost certain that the means of giving such warning were at our disposal had we been on the alert and able to interpret the signs aright.

On this subject we cannot do better than refer our readers to the several letters communicated to these columns by our valued correspondent, the Superintendent of the Eastern Telegraph Company's station at Zante. Mr. Forster has set an excellent example of steadily observing the magnetic phenomena accompanying the volcanic or earthquake disturbances of the region in which he is stationed. His letters will be found in *The Electrician* of May 14, 1881, April 28 and December 1, 1883, and April 5 of this year. In the second of these letters the spirit in which he is pursuing his observations is sufficiently illustrated by the following passage:—"After careful observation I came to the conclusion, and communicated it to several of my people, that within twenty-four hours we should have a violent shock of earthquake . . . . . and to my extreme delight we had at 4:10 a.m. (next morning) one of the smartest shocks felt for the last two years." Perhaps we in these peaceful regions can hardly enter into the enthusiasm of this "extreme delight," but we can appreciate it; and if a little more of the same spirit were encouraged in all quarters that are conveniently situated for studying earthquake phenomena we should soon know more about them, and their terrible effects might not improbably be mitigated. Mr. Almond, of Candia, is also studying the subject, as will be seen by his letter in *The Electrician*, June 2, 1883.

Only by the accumulation and comparison of facts such as these officers are collecting in the Mediterranean can

Digitized by Google

we ever hope to arrive at some satisfactory explanation of earthquake phenomena. It is natural that an individual worker will start with a theory of his own; but for general observers there should be no theory at all. It would be unsafe to conclude that because magnetic disturbance precedes subterranean dislocation that the latter is the result of the former; we can only say that we observe the one before we feel the other. We can readily understand that the shifting of any large bulk of the earth's interior would affect the polarity of neighbouring magnets; we cannot at present understand how any change in the earth's magnetism would of itself occasion gigantic internal commotion in the earth itself. We want more facts bearing upon the prime origin of the observed magnetic perturbations; similarly as regards the connection between volcanic eruptions and neighbouring earthquakes. Some very interesting evidence on this point will be found in Mr. Forster's third letter, pointing to the occasional undermining effects of eruption, extending probably over very large areas, resulting in collapse, otherwise earthquake, only where towns have been built, so to speak, over the upper shell. The mere shock of earthquake, as it is called, may be due to the distant effects of underground slip or tumbling in of undermined areas causing a tremor at the earth's surface, startling in its character, especially if rarely experienced, but by no means dangerous. The British Isles will bear a vast deal of this kind of shaking before anything serious comes of it, especially in these days of jerry building; for it is a painful fact that seismic ethics do not favour honest building. Lath and plaster are perfectly safe where solid masonry is inevitably doomed to destruction. Let us hope that before this indiscriminate intruder visits our shores again we shall be so far advanced in knowledge as not to be taken unawares by its vagaries. It is a notable fact, however, that not the slightest electrical disturbance of any kind was observed upon the land or submarine lines connected with this country on the morning of Tuesday last, although the current needles at Greenwich and the magnetographs at Kew were slightly affected.

## THE SCHUCKERT PATENT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention having been called to several letters which have appeared in your correspondence columns, entitled "A Question of Patents," I claim your indulgence to offer the following statement of facts through the same medium.

Though my agent has been negotiating with the Brush Corporation, in 1881, I never gave my final consent to the sale of my letter-patent, nor did I sign any document, and I never have received any payment on this behalf. I therefore must suppose the Brush Corporation to be in an error, or some incorrect action on the part of my agent must have occurred.—Yours, &c., S. SCHUCKERT.

Nürnberg, April 16, 1884.

## ELECTRIC CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the important and interesting paper on this subject by Mr. W. Geipel in your issue of April 12, I wish to draw attention to a point which I do not think Mr. Geipel has given sufficient prominence to. I allude to the variations of potential due to the resistance of the conductor.

In the regulations for the public supply of electricity (Chelsea Provisional Order, Clause 29) it is specified that the variations in "pressure" at any part of the circuit must not exceed 5 per cent. under or over a stated pressure; in other words, the difference of potential between any one point in the circuit and a corresponding point must not vary more than 10 per cent.

Given a varying supply and a constant pressure at the source of the supply, it is evident that any variations of pressure in the circuit can only be due to the varying current $c$ passing through the constant resistance R, or $e = C R$ and $e_1 = C_1 R$ when $e$ equals the loss of E.M.F. in the conductor.

It is therefore manifest that in order to fulfil the above condition with a current varying from one to $n$ amperes – N R must not exceed 10 per cent. of the E.M.F. at the source of supply.

In the following table I have worked out a few examples, which, if compared with Mr. Geipel's table, will show the importance of taking *length* into consideration.

SECTION OF CONDUCTORS IN SQUARE INCHES—THAT THE LOSS OF E.M.F. MAY EQUAL 10 PER CENT.

| Current in amperes. | Distance from source of supply in yards. | | | | |
|---|---|---|---|---|---|
| | 100 | 500 | 1,000 | 3,000 | 7,000 |
| 100 | ·0233 | ·1165 | ·233 | ·699 | 1·631 |
| 150 | ·0349 | ·1747 | ·349 | 1·049 | 2·446 |
| 200 | ·0466 | ·233 | ·466 | 1·398 | 3·262 |
| 300 | ·0699 | ·349 | ·699 | 2·097 | 4·893 |
| 700 | ·1631 | ·815 | 1·631 | 4·893 | 11·417 |
| 2,000 | ·466 | 2·33 | 4·66 | 13·98 | 32·62 |
| 6,000 | 1·398 | 6·99 | 13·98 | 41·94 | 97·86 |
| 50,000 | 11·65 | 58·25 | 116·5 | 349·5 | 815·5 |
| 70,000 | 16·31 | 81·55 | 163·1 | 489·3 | 1141·7 |

The formula used was

$$S = \frac{a l C E}{100 p},$$

where

S = Section of conductor in square inches,
$l$ = Length of conductor in yards,
C = Current in amperes,
E = E.M.F. in volts,
$a$ = Resistance of 1 yard of conductor; 1 square inch in section = ·0000233ω,
$p$ = Loss of E.M.F. allowed in volts.

Yours, &c.,

London, 16th April, 1884. N. M. ARNOT.

## UPWARD LIGHTNING DISCHARGES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: From the stress laid on the *upward* direction of lightning discharge at Antwerp Railway Station, referred to in *The Electrician* of the 12th inst., and having only seen one other case mentioned, I am led to infer that such discharges are very unusual—or at least not often recorded. As against that supposition, my father, who for many years lived on an eminence, and took a deal of interest in observing natural phenomena, tells me that he *very often* saw upward discharges of lightning, and that they were of a yellow tint, whereas discharges from the atmosphere were usually of a blue tint.

I should be glad to learn through your columns if others have noticed that this is so.—Yours, &c., D.

## SMALL DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have made a small Siemens H dynamo machine 6in. high and 4in. wide. The field-magnets I have wound with 2lb. of No. 18 C.C. wire on each limb, and the armature I have

Digitized by Google

wound with ½lb. No. 20 silk covered wire. And I want to know if some kind brother reader will put me right and say if I have got enough on the field-magnets in proportion to what is on the armature; and if not, will you say how much 18 C.C. wire I am to wind on the field-magnets.

W. H.

## ELECTRIC LIGHTING OF TOWNS.

Four lectures on "The Electric Lighting of Towns" have recently been given in the large theatre of University College, Nottingham, by Professor Garnett. The lectures are worthy of mention, because it is seldom that so large a collection of electric lighting appliances has been exhibited in the provinces.

The first lecture was of course mainly devoted to principles. Magnetic lines of force depicted in iron filings were projected on a screen 14ft. square, and the filings were seen to arrange themselves on the screen under the action of the magnetic field. In this way the effect of iron in the field was illustrated, as well as the field of force of the Gramme machine, and it was shown that there was no sensible magnetic force within the Gramme ring. A three-light Brush machine and Brush regulator were exhibited, dissected, upon the table, and the principle of the regulator explained by means of a number of blocks of carbon introduced into the circuit of some lamps, when it was found that the lamps could be made to burn with any degree of brilliancy by altering the pressure on the carbon blocks. In the second lecture the lecture table was illuminated by 16 Swan lamps, the current for which was supplied by the Brush machine previously shown. Photographic views of all the principal dynamos and arc lamps were projected on the screen, and a 200-light Ferranti machine with its Siemens exciter were shown upon the lecture table, the Ferranti being dissected so as to show the armature and collectors, while all the magnetic poles were marked with red or blue discs according to their polarity. A large wooden model of the Gramme machine wound with thick white cord, in place of wire, was used to illustrate the methods of winding and the difference between series, shunt and compound dynamos. The effect of the Gramme ring was illustrated by reference to railway travelling. Most persons would prefer travelling thirty miles by rail to going ten miles by any other means. A person going from his house in Nottingham to meet an engagement in the city of London would probably take a hansom to one of the railway stations, thence take the train to St. Pancras or King's Cross, and again take a hansom to his destination. In the same way the magnetic lines of force go from one pole piece across the air to the Gramme ring or railway, and journey through that till they get as close as possible to the other pole-piece, when they dart across the air to it. Between Nottingham and London there are two good lines, viz., the Great Northern and the Midland, and a traveller may journey by either, his choice being sometimes determined by considering which of the stations is nearer to hand. So the lines of force may pass along the upper or lower portions of the Gramme ring, their "choice" being determined by the positions on the pole-pieces from which they start. During the lecture a Serrin lamp was ignited, and at the close the theatre was illuminated by two Brush lamps, driven by the Brush machine before referred to.

The fourth lecture was little more than a repetition of the third, given for the benefit of those who were unable to gain admission to the third lecture. Nevertheless the theatre was again crowded. The lecture table and space behind had been converted into a drawing room, 30 feet in length, which was lighted by Swan lamps, most of them ordinary 20-candle lamps, but some of them were 40-candle lamps, the glass bulbs of which were ground. These lamps had been specially constructed for the Hammond Company for lighting lace machines, but their effect in the drawing room was much admired. Some of the lamps were 123 volt lamps, and could be lighted or extinguished singly; others were 41 volt lamps, arranged in threes. Above the lecturer's table was a triplet of 20-candle lamps, silvered over their upper surfaces by Messrs. Lorrain and Waters. These lamps are very useful for billiard rooms or offices where it is desired to send all the light downwards to the table or desk, but they are also particularly valuable in an engineer's fitting shop. The fitter can place the lamp near to his work, and send all the light upon his vice, while the silver surface completely protects his eyes from the glare of the filament. The turner can send all the light from the lamp into the hole he is boring, and place his face close to the lamp without singeing his hair or injuring his eyes. In front of the drawing room was suspended a corona containing 15 coloured lamps, and 30 other coloured lamps were suspended in festoons below the frieze, giving a fairy-like aspect to the foreground. These lamps were all coloured by a new process, invented by Mr. Simpson, the demonstrator of physics in the college, by which the most brilliant coal tar dyes can be employed, and ordinary Swan lamps coloured at a nominal cost. The dyes actually employed were magenta, malachite green, eosin, primrose, and methyl violet, and the lamps were in as good condition when taken down after more than a week's exhibition as when first put up. The process has of course been protected, and will prove very useful for exhibitions and theatre illuminations. The back of the theatre was illuminated by six 40-candle lamps on an electrolier suspended from the roof. All the incandescent lamps were lighted by the Ferranti machine previously exhibited. As the audience assembled the theatre was illuminated by two Pilsen lamps running on the Brush circuit, and two sun lamps *burning in parallel arc* on the circuit of the Ferranti machine. The walls of the drawing room were covered with claret velvet and tapestry, which produced a very pretty effect.

The lecturer having exhibited the principal portions of the sun lamp explained that all arc lamps which are not provided with the means of regulating their own current are dynamically unstable, for if the current is increased the temperature is also increased, and the resistance consequently diminished, which of course leads to further increase of current. By connecting a sun lamp directly with the Ferranti machine (which gave the proper E.M.F. for the lamp) he had melted a large portion of the marble block without calcining it, and on cooling the fused calcic carbonate cystallised in beautiful crystals, forming long needles radiating from the mass. When two or more such lamps are placed in parallel arc one gets the advantage over the other and steals the current from it. The lamps exhibited had been regulated by the introduction of two ohms of iron wire with each lamp. When increase of temperature reduced the resistance of the lamps the increased current increased the resistance of the iron very much, and thus more than compensated for the lowering of the lamp's resistance. Such regulation of course involved waste of power, but when it is desired to run one or two sun lamps in parallel arc with a number of incandescent lamps the waste of power may be more than compensated by the advantages gained in having but one dynamo and set of mains.

The two sun lamps all the time they were burning sang each a powerful note of about 450 vibrations per second. The lecturer explained that he had examined the orange-coloured flame, or solar prominence, proceeding from the lamp with a rotating mirror, placing the mirror so that the light from the marble crucible, or photosphere, was screened off by the frame of the lamp, while that from the prominence fell on the mirror. On spinning the mirror an orange band, due to the calcium flame, was observed, and above and below the orange a blue band, succeeded by a green band, but this compound band was not continuous; it was intercepted at intervals by black spaces cutting across the whole band, and showing that the flame entirely disappeared at every alternation of the current. The Ferranti machine was running at about 1,750 revolutions per minute, which corresponded to about 467 alternations per second, and this successive appearance and disappearance of the flame produced the note heard. A Jablochkoff lamp, with globe and corona, was then shown, and a candle ignited by the Ferranti current (properly regulated to suit the candle). The candle burned with extreme regularity, diffusing a beautiful rose-coloured light. The necessity for using alternating currents was shown by allowing the Jablochkoff candle to burn for a

Digitized by Google

short time with the Brush current, when one carbon burnt half an inch below the other; and the necessity of properly regulating the current was made manifest by coupling the candle direct with the Ferranti machine for a few seconds, when a white flame, about as big as that produced by a six-foot gas burner when flaring, but with an illuminating power of many thousand candles, was produced. This current heated the whole candle to redness, and melted off the copper coating. The effect of this was very marked when the proper current was again sent through the candle, which then burned with far less steadiness and beauty.

The whole of the incandescent lamps in the theatre were then illuminated, and the lecturer explained some of the merits of the Ferranti and Victoria dynamos, a 10-light Victoria machine being exhibited. For lighting purposes only the Ferranti is extremely simple, and having only collectors instead of commutators, it requires practically no attention beyond filling its lubricators. Also the alternating currents produced enable the lamps to last longer than continuous currents, but they cannot be employed for motive purposes. Connecting an electro-magnet with the Ferranti circuit, the lecturer showed that it exerted no attraction for its armature which could be detected, while the rapid lengthening and shortening of the cores as they were magnetised and demagnetised caused the magnet to sing a note *which could be heard all over the theatre*, and which was the same as that of the sun lamps. Though the magnet had very little resistance indeed, yet a comparatively small current passed through it, as was shown by coupling it with some lamps. Lights can be regulated with alternating currents by introducing a coil of wire of very little resistance into the circuit, and inserting an iron core to a greater or less distance into the coil, when "self-induction" reduces the current. (It was shown in the second lecture that with the Brush current the introduction of the electro-magnet between the mains caused nearly all the current of the machine to pass through it.)

The use of safety fuses to obtain security against fire was then illustrated, and the lecturer pointed out that the heating effects of the current in a wire might be made of service in providing hot coffee in the early morning. It is only necessary to have a few ohms of platinum wire wound on a porcelain frame, to introduce the coil into the cup of coffee and turn on the current, when the coffee will be ready before the toilet has sensibly progressed. Nearly three-quarters of a pint of water was raised to boiling from the temperature of the air by the Brush current in about three minutes. The risk of injury from shocks was next dealt with, and the lecturer invited the audience to handle the mains after the lecture to prove that the shocks would not be fatal (unfortunately no one accepted the challenge), and stated that a limit for E.M.F. somewhat above that fixed by the Board of Trade might be allowed with absolute safety. The Victoria machine was then shown running as a motor and driving a Gramme machine which lit a Swan lamp to over 20 candle-power.

Lastly, the question of expense was dealt with. The lecturer stated that he had come to the conclusion that a company might carry on a remunerative business in Nottingham if they could obtain a rental of 25s. per lamp per annum for the greatest number of lamps alight at one time. The whole capital outlay and a very large portion of the annual expenditure of an electric lighting company depends on the *greatest number of lights required at one time*, and not upon the number of hours they are burning. With gas at 2s. 6d. per 1,000 cubic feet in an ordinary provincial town the gas return is about 13s. per lamp (on the average) for the number of lights going in the early part of a winter's evening. In a house with a rental of £100 a year the gas bill for illuminating purposes only may be about £12, and the number of lights required at once is about 20 under ordinary circumstances. For the electric light in such a house about £25 per annum would have to be paid, but the difference would be more than saved on the decorations, curtains, books, pictures, and nearly everything else in the house, so that from a financial point of view alone incandescent lighting is preferable to gas. Of course, the question of health is entirely on the side of electric lighting.

In factories where arc lamps are not unsuitable the cost of Brush lamps would be about 2d. per hour against 1s. 6d. for the same amount of light from a sun burner supplied with gas.

The drawing room, with the installation of incandescent lamps, was on view at intervals during a week, and many persons availed themselves of the opportunity offered to inspect the arrangements and make inquiries.

The Ferranti dynamo, exciter, and many of the electroliers, and brackets, switches, lamps, &c., were lent by the Hammond Company; Messrs. Faraday and Son lent a very pretty corona, some wall sconces, and other fittings; the Brush Midland Company lent the Brush machine, the Brush and Pilsen lamps, the regulator, and some other appliances; the Anglo-American Brush Corporation furnished the small Victoria machine and some other exhibits; the Sun Company lent two Sun lamps; the Jablochkoff Company the Jablochkoff lamp complete, with supply of candles and separate candle holder; the Edison Company a meter, specimens of mains, service box, switches, and other fittings; while Messrs. Foster and Cooper, a local firm of upholsterers, furnished the drawing room. The power was supplied by the Robey engine employed in the Technical Schools.

---

## THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

### INAUGURAL ADDRESS.

Delivered by Professor W. GRYLLS ADAMS, F.R.S., 10th Jan., 1884

(CONTINUED FROM PAGE 548.)

Having considered the efficiency of the dynamo machines for converting mechanical energy into electrical energy, which may be regarded as another form of energy of motion, we have now to consider the reconversion of this electrical energy back again into heat and into energy of radiations, as we compare the candle-power with the energy expended under different conditions in incandescent lamps.

*Method of Testing the Incandescent Lamps.*—A current from a Grove battery was sent through the lamp to be tested and the current-meter in

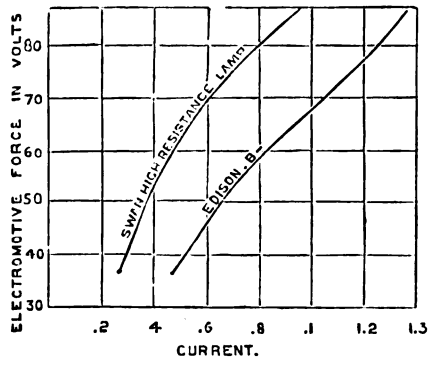

FIG. 6.

simple circuit, the lamp being in its place on the Bunsen photometer. Wires were carried from the two electrodes of the lamp to the key employed for discharging the condenser through the reflecting galvanometer, and wires from the same electrodes were also connected to the voltmeter. The positions for the equality of illumination in the photometer were found for red light and for green light by looking at the photometer through red and green glasses respectively. The illuminating power of the standard lamp with which the incandescent lamps were compared was determined to be 17·5 candles. At first a set of observations was made simultaneously by the different observers with, say, 20 cells of Grove, then 5 cells more were added and the observations repeated, then 5 cells more, and so on up to 40 or 50 cells or higher. In some cases experiments were carried to the breaking point, or giving way of the lamp, when it was found that the lamps of each maker had their own distinctive peculiarity. By making the tests in this way we were able to determine the characteristic, and to plot the characteristic curve for each lamp—a curve in which the energy absorbed is measured horizontally and the candle-power measured vertically.

The values of $\frac{E}{C}$, or the resistance of the lamps, show clearly that there is a point which is reached in the case of the Edison lamps when their resistance diminishes no further, but begins to increase as the current increases. If we draw the curve with the current for the abscissa, and the E.M.F. for the ordinate (Fig. 6), we see where the resistance begins to increase by a change in the direction of curvature of the curve. Probably at this point the carbon filament begins to give way at the junction with

Digitized by Google

the copper, for it is generally found that this is the point which first yields in the Edison lamps. In the case of the Swan lamps this critical point was not reached, and the curvature continues to be in the same direction to the extreme point tested.

The characteristic curves for the principal incandescent lamps are given in Fig. 7, the values of electromotive force being the mean of the values given by the voltmeter and by the discharge from the condenser E C, the energy expended being the product of the values of the current and electromotive force so determined.

The characteristic curve for the Edison B lamps shows that at 10 candle-power the Edison lamp yields 150 candles per horse-power. As the illumination is increased the yield increases. At 16 candle-power there are 5·7 kilogrammètres and 211 candles per horse-power. At 32 candle-power there are 7 kilogrammètres and 342 candles per horse-power. At 40 candle-power 7·5 kilogrammètres are absorbed, and there is a yield of 400 candles per horse-power. Comparing this with the Swan lamps, we see that an absorption of 7·5 kilogrammètres gives 60 candle-power in each lamp and a yield of 600 candles per horse-power. The characteristic curve for the Swan lamps shows that at 10 candle-power there is a yield of 200 candles per horse-power. At 16 candle-power there are 4·4 kilogrammètres absorbed, and a yield of 272 candles per horse-power. At 32 candle-power there are 5·8 kilogrammètres absorbed, and a yield of 415 candles per horse-power. I have employed these numbers for the sake of comparison with the results arrived at in Paris by Professor G. F. Barker and Mr. Crookes, and given in Vol. XI., p. 229, of our *Journal*. As might be expected, the economy of all incandescent lamps is greater at high than at low incandescence. This might be expected, since there must be a certain quantity of energy used up in the radiation of dark heat from the carbon filament, when the temperature is not high enough to make it glow, and this dark heat is not increased so greatly in amount when the filament has reached the temperature at

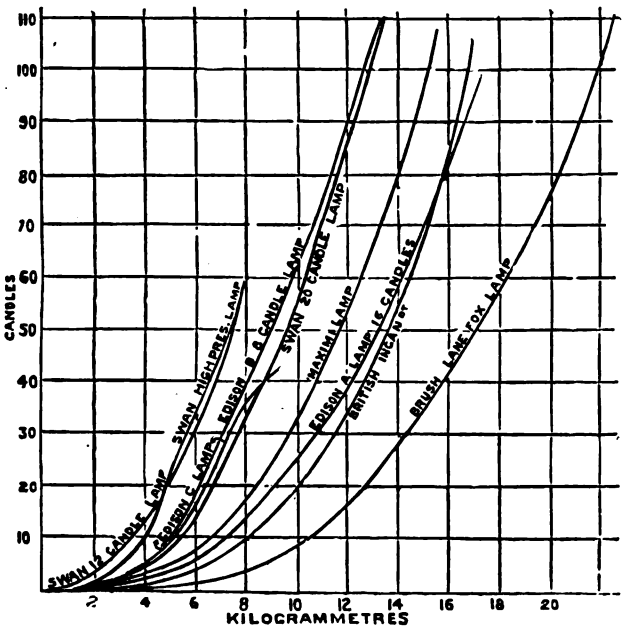

FIG. 7.

which it gives a brilliant light. The comparison of the characteristic curves of Swan high-resistance and low-resistance lamps with Edison B lamps does not seem to support the statement that "the economy of light production is greater in high-resistance than in low-resistance lamps;" for the economy of Swan No. 13, whose resistance cold is 194 ohms, and Swan No. 16, whose resistance cold is 20 ohms, is very nearly the same, the curves crossing one another; and both of these are more economical than Edison B lamp, whose resistance cold is 136 ohms.

These experiments clearly show that the economy of light-production is not necessarily greater in high-resistance than in low-resistance lamps, but is rather a function of the material of the filament and the way in which that filament is made. Swan's 200 ohm and his 20 ohm lamps are shown to be nearly equal in efficiency, the resistance of the first when giving an illumination equal to that of 37 candles being 102 ohms, and of the second less than 10 ohms. The other low-resistance lamp, which is nearly of the same efficiency, and more efficient than any of the Edison lamps or of the lamps of other inventors, has a resistance of about 13 ohms when giving the same illumination of 37 candles.

These results show that the question of constructing incandescent lamps of high or low resistance must be decided entirely by the economy of distribution of electricity. In the case of the high-resistance lamp, the current for 37 candles is only about three-fourths of an ampere, whereas the current for the same illumination from the low-resistance lamps is at least three times as great, or 2¼ amperes.

We have still to consider the re-conversion of electrical energy back into mechanical work by means of a motor dynamo machine. If two dynamo machines be placed on the same electric circuit, and one of them be set in motion to generate a current of electricity, part of the energy of the current will be spent in heating the conductor throughout the circuit, and another portion will be spent in setting the other dynamo in motion in such a direction as to produce an opposing electromotive force in the circuit.

The previous equations for dynamos are modified, and the extension of Ohm's law gives $E = e + C R$, where $e$ is the opposing electromotive force of the motor dynamo and R the total resistance of the circuit. We have also the equation $E C = e C + C^2 R$ connecting the different portions of the electrical energy. Here $e C$ is the number of units of electrical energy which may be converted into mechanical work by means of the axle of the motor dynamo. The ratio, $\frac{e}{E}$, may be termed the electrical efficiency of the combination. The equation $e = E - C R$ shows that for the same electromotive force of the generator, *i.e.*, for the same rate of revolution, the contrary electromotive force of the motor, and consequently the speed of the motor, diminishes as the resistance of the circuit increases. The effective work $e C$ is greatest when $e C = C^2 R$, *i.e.*, when the electrical efficiency, $\frac{e}{E}$, is ½, *i.e.*, when one dynamo revolves at half the speed of the other, supposing the dynamos to be alike.

The electrical efficiency will then be the ratio of the rates of revolution. So much progress has been made in the re-conversion of electrical energy into mechanical energy, or energy of motion, during the past year, that I must include some notice of it in my address.

The use of dynamo machines for the transmission of power to considerable distances has now been accomplished, the loss in converting electrical into mechanical energy being no greater than in the reverse action. Electrical and mechanical energy being two modes of the energy of motion which are mutually convertible, the only loss is that due to friction and the heating of the wires. We have seen that the external or commercial efficiency of the best dynamo machines is 88 or 89 per cent.—say, 88 per cent. Taking the same efficiency for re-conversion, the twofold conversion may be effected with an efficiency of 77·5 per cent., *i.e.*, with a loss of 22·5 per cent. But the conductors will absorb some energy as heat through their electrical resistance, the amount depending on the length of the conductors and on the current which they have to carry, *i.e.*, upon the work which the motor is required to do; allowing 5 per cent. for this will still leave a mechanical efficiency of 72 per cent.

Visitors to the Electrical Exhibition in Paris cannot fail to have been struck with the great variety of applications of electrical energy which had already been made by M. Marcel Deprez, and they will not have been astonished at the later results at Munich, again at Paris, and the much greater success attained within the last few months at Grenoble.

The objections which were urged with regard to the two machines in the experiments at the Chemin de Fer du Nord in Paris, that they were placed close together, can have no place in the Grenoble experiments, where the dynamo machines were placed 14 kilometres, or nearly nine miles, apart. In these experiments wires of the new material, siliceous bronze, of two millimetres diameter, were employed as the conductors, and greater attention was paid to the insulation of the two machines. The power was applied to the generating machine from a turbine, and was measured from time to time by means of a Prony friction-brake, the velocity of the turbine being the same as in the running of the dynamo machine.

As one result of the experiments carried out by the committee, it has been shown, experimentally, that the efficiency increases with the velocity of rotation of the generating machine (as the formula

$$\rho = \frac{1}{1 + \frac{R}{n\,(a + b\,m + c\,m^2)}}$$

would give). Their experiments have also shown an electrical efficiency of from 60 to 70 per cent., corresponding to a commercial or mechanical efficiency of conversion of from 50 to 62·3 per cent.

In these experiments the velocities of revolution were so high that the magnetic fields of the machines were near their points of saturation, and so might be regarded as no longer varying with the current.

The opening of the Portrush Electric Railway in September last, and its practical working, show that in our own country Sir William Siemens has not been behind in the practical applications of electrical energy. A separate conductor is placed at the side of the railway to carry the current, the return circuit being completed through the rails themselves. The power is obtained by means of turbines from a waterfall with a head of 24 feet. The electrical conductor is maintained at an electromotive force of 225 volts. The resistance of the conductor per mile is ·23 ohm; and, with four cars running, requiring 4 horse-power each, the loss due to resistance does not exceed 4 per cent. of the power developed on the cars. In his paper on this railway Mr. A. Siemens has shown the use which may be made of characteristic curves of dynamos when the object is to find what arrangement of dynamo machines is best adapted to perform any given work.

We see, then, that by means of the dynamo machine mechanical work may be converted into electrical energy, and that in the form of the electric current as much as 88 per cent. of the total energy expended can be usefully employed in the external electric circuit in producing heat (as in the electric furnace) or light (as in arc and incandescent lamps). Or this energy may be conveniently transmitted to a distance from its source and may then be converted back into mechanical work, giving out again more than 60 per cent., or even 70 per cent., of the mechanical work originally spent in its production. We may see

*The Dynamo Machine,*
Piercing with the little diamond
Deep into the mountain side,
Then, retiring, give the spark,
And with a shock the rocks divide.

Digitized by Google

Then he lifts the heavy masses,
Melts and moulds the iron way,
Sheds his light, and with his burden
Rushes to the open day.

## SUPPLEMENTARY NOTE.

*The Testing of Dynamo Machines and Incandescent Lamps.*—The experiments at the Crystal Palace on gas engines and on dynamo machines were carried out by the same committee, consisting of Mr. Horace Darwin, Mr. F. J. Sprague, Mr. Spagnoletti, Mr. Crompton, and myself, Mr. F. J. Sprague devoting himself most zealously to the work.

The engine supplying the power to drive the dynamo machines was kindly lent by Messrs. Davey, Paxman, and Co. It was a semi-fixed single cylinder engine, which ran very regularly, and was capable of giving from 40 to 43 horse-power in the cylinder, and did not use in the various experiments more than from 1½ to 3 horse-power for friction.

The transmission dynamometer and the electrical apparatus for testing were kindly lent by Messrs. Latimer Clark, Muirhead, and Co.

*The Dynamometer* (Fig. 4).—The two parts of the belt from the engine fly-wheel passed between two 9in. pulleys, A, A, which are mounted in a frame attached to a fixed standard to the pulley Q on the shaft. The frame supporting the pulleys was supported at one end of a long lever, U, T, and counterpoised. The lower belt was the driving belt, and the pull upon the end of the lever was equal to the difference of the tensions of the lower and upper belts resolved at right angles to the line joining the centres of the fly-wheel and the shaft Q. The centre of the fly-wheel was nearly on a level with the floor, so that the line joining the centres of the fly-wheel and shaft was inclined 2° to the horizontal. The lineal speed of the belt varied from 44 to 51 feet per second, and the difference of tension on the two parts of the belt was as much as 250 to 300lb. for the heavier loads. Near the pulleys A A, and between them and the shaft, a wooden frame, G, was erected, consisting of two uprights on opposite sides of the belt with a crosspiece.

This was the support for a lever, V, made of iron of an inverted T section, I. Through this were secured square bars of iron, $u$ and $u_1$, for knife edges. To the one at the end of the lever $u_1$ was hung a shackle connected with a link, $k$, and side adjusting screws to the pulley frame U. The distance between these knife edges was 2′ 6″. The other end of the lever was prolonged about 10ft, and the end allowed 3in. or 4in. play each side of the horizontal by wooden bars. When horizontal the pulley frame was very nearly in its true middle position, and a deviation of one inch either way sufficient to throw the end of the lever to the extreme limit allowed with a load on. The lever being horizontal, a slight pressure of the finger would destroy the equilibrium. The weight of the frame and pulleys and the drag of the lower belt when at rest was counterbalanced by the weight J.

To determine the constant of this dynamometer, and to consider its accuracy,

Let R = radius of fly-wheel = C E = 42½in.

$r$ = radius of shaft pulley = Q $b$ = 14½in.

C = distance between faces of dynamometer pulleys = $m\,m'$ = 1¼in.

$k$ = thickness of belt.

D = distance of centre of fly-wheel to middle of dynamometer = C S = 20ft. 9in.

$d$ = distance from centre of shaft pulley to middle of dynamometer = Q S = 7ft. 6in.

$t$ and $t_1$ = tension of lower and upper belts.

$p$ and $p_1$ = corresponding pulls at right lines to line of centres.

P = resultant *vertical* pull.

$l$ and $l_1$ = short and long arms of lever.

$2\alpha$ = right enclosed angle.

$2\beta$ = left enclosed angle.

$s$ = speed per minute of rim of shaft pulley.

$n$ = number of revolutions of shaft pulley per minute.

W = balancing weight at distance of 1ft.

$\theta$ = 2° 36′ = the angle of inclination of line of centres to the horizon.

We have: $$\alpha = \sin^{-1}\cdot\frac{R-\frac{1}{2}(c-2k)}{D} = \sin^{-1}\frac{R-\frac{c}{2}+k}{D} = 9°\,45'.$$

$$\beta = \sin^{-1}\cdot\frac{r=\frac{c}{2}+k}{d} = 9°\,4'.$$

$$p = t(\sin\alpha + \sin\beta). \qquad p_1 = t_1(\sin\alpha + \sin\beta).$$

$$P = \frac{1}{l}W = (p - p_1)\cos\theta = (t - t_1)\cos\theta(\sin\alpha + \sin\beta).$$

Whence $$(t - t_1) = \frac{1}{l}\cdot W\frac{\sec\theta}{\sin\alpha + \sin\beta}.$$

The work transmitted to the shaft pulley per minute is

$$(t - t_1)s = (t - t_1)\cdot\frac{2\pi r n}{12}.$$

Now sec. $\theta$ = 1 nearly, and

$$\sin.\,\alpha + \sin.\,\beta = \sin.\,9°\,45' + \sin.\,9°\,4' = \cdot32693.$$

Hence the work transmitted per minute is

$$\frac{1}{l}\cdot W\,n\cdot\frac{2\pi r}{12\times\cdot32693} = W\,n\times 9\cdot289$$

and the transmitted H.P. is $W\,n\times\cdot000281$.

In practice the driving part of the belt becomes tight and the upper belt becomes slack, and the part of it between the dynamometer and the fly wheel, on which there is very little tension, will drop very considerably. In some of the experiments, when there was a heavy load, I noticed that at the dynamometer it dropped quite to and sometimes below the horizontal. This would only occur with large loads, when there was very little tension on this part of the belt, and therefore the error from this cause would be small. The speed was measured on the shaft pulley Q, and the moment of the balancing forces on the long arm of the lever equals W, the force which at a distance of one foot will balance the pull on the shorter arm of the lever.

*Electrical Testing.*—Two beams, A A (Fig. 5), about 10ft. long, were fixed about 10ft. apart on four posts. Across these were wound 26 coils of No. 16 galvanised iron wire. Each coil was about 60ft. long, had three full turns, and had a resistance (when cold) of about 1·5 ohm. All the like ends were taken to one point, F, in the middle of a third beam, E F D, where connection was made with a short piece of rubber-covered tarred and taped wire, which led to the resistance coils R.

The other ends in two sets were taken to two mercury cups, E and D, connected by a short piece of cable, $p$. In the cup E was inserted one of the mains from the dynamo. In this way the current could be sent over from one to twenty-six parallel and nearly equal circuits. One of Helmholtz's double coil tangent galvanometers, N, kindly lent by Elliot Brothers, was placed in one of the circuits, a little removed from the rest. About 3·5 amperes gave a deflection of 45°, and in each experiment the number of circuits was arranged so as to give usually a deflection of from 35° to 55° on the galvanometer. In one or two cases higher deflections were unavoidable. With these currents the wire, being freely exposed, only at times warmed to the touch. Immediately after an experiment the resistance of these wires was taken, and in no case was there an increase in resistance of more than one per cent.

There were three methods of measuring the current:—

1. The wires on the frame being supposed to be of equal resistance, equal currents would flow in them, and the total current would be equal to the current in the galvanometer multiplied by the number of wires used.

$$C = n\,k\tan.\,\theta. \quad . \quad . \quad . \quad . \quad . \quad . \quad (a).$$

2. Supposing the wires not to be quite of equal resistance, then if $m$ = the resistance in parallel circuit of all the wires used, when cold, and $g$ that of the galvanometer circuit, when cold,

then $$C = \frac{g}{m}\,k\tan.\,\theta. \quad . \quad . \quad . \quad . \quad . \quad . \quad (b).$$

3. The difference of potential at the terminals of the galvanometer circuit, being equal to the product of the current and the resistance of the wire at that instant, *i.e.* when warm,

or $$E = C'\,g' = g'\,k\tan.\,\theta;$$

or, if $m'$ is the resistance of all the wires, when warm,

$$E = C\,m' \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (c).$$

The difference of potential E was measured by a condenser and reflecting Thomson galvanometer. Even if the wires are not equal, (*b*) and (*c*) should give results which are very nearly equal.

German silver would have been preferred to galvanised iron for the wire frame, if it had been available, because of its more even quality, higher specific resistance, smaller change of resistance for change of temperature. There could be very little leakage from one wire to another, for the extreme difference of potential at the ends of the wires was only about six volts.

The external resistances used were (1) coils of coarse German silver wire arranged in multiple circuit, and arranged so that a portion could be cut out or short circuited to give the required resistance; or (2) boards wound longitudinally with fine iron wire and laid over one another in a large tub, the ends being connected and the bights brought to the edge of the tub clear of each other. Water was allowed to run into the tub and the circulation kept up during the experiments.

One end of the short cable was connected to one end of these wires and the return main to the dynamo, hooked into the bight at such distance as was required to give the proper strength of current. For higher resistances the resistance of water between a piece of sheet iron and an iron tube was employed.

The galvanometer G (Fig. 5) had a resistance of about 11,000 ohms, and the condenser C had a capacity of ½ a microfarad. H is a shunt, P a reversing key, and T a discharge key. During the later experiments an Edison incandescent lamp, L, was used instead of an oil lamp for the reflecting galvanometer. The instruments used for the potential and resistance measurements were kindly lent by Messrs. Clark, Muirhead, and Co. Clark's standard cell (E.M.F. = 1·457 volt) was used for standard deflections, and compared with it a pint Grove cell had an E.M.F. of 1·925 volt. Galvanometer circuit had a resistance of 1·559 ohm cold.

*To Determine the Constant of the Tangent Galvanometer.*—A branch current from an "A" Gramme machine was sent through the thick

Digitized by Google

German silver coil and the tangent galvanometer, and the difference of potentials at the terminals was taken by the condenser and compared with the standard cell, no shunt being used with the reflecting galvanometer in either case. The mean of a great number of different determinations gave $k = 3{\cdot}469$ for the constant of the tangent galvanometer. Three sets of readings of the dynamometer were taken—

(1). For friction of shafting alone.
(2). For shafting and dynamo running free.
(3). For shafting and dynamo with circuit closed.

The resistances of the dynamos and of the branch wires and the deflections given by the standard cell were taken during the two first experiments, and the electrical measurements with the dynamo running were made during the third experiment. A relation was established between the deflections given with the different shunts of the galvanometer by means of 12 Leclanché cells. After the standard deflections were obtained the difference of potential at the brushes of the commutator or at the terminals of the external circuit were obtained, and then the difference of potential at the points E and F, the terminals of the galvanometer circuit. After this the engine was indicated and the speed of the dynamo found. Then, as soon as the current was broken and the dynamo stopped, the resistance of the armature and the field magnets was obtained.

(TO BE CONTINUED.)

## EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY (LIMITED).

The twenty-first ordinary general meeting of this Company was held on the 23rd inst., at the City Terminus Hotel, Cannon-street, London, under the presidency of John Pender, Esq., M.P.

The SECRETARY (Mr. F. E. Hesse) read the notice convening the meeting and the minutes of the last meeting, which were confirmed by the present meeting and signed by the chairman as correct.

The report of the directors was taken as read.

The CHAIRMAN said: Gentlemen, probably at no time have we issued a report so full of information as the one now before you, and which makes it unnecessary for me to address you at any great length to-day. Nevertheless, although the information in the report is so complete as to the work done during the past six months, I think there are some points which I may require to explain, and which I have generally done on previous occasions; and as I think it is a good rule I will not make an exception on the present occasion. The gross receipts for the half year ended 31st December, 1883, amounted to £231,056, against £209,131 for the corresponding period of 1882, showing an increase of £21,925. The working expenses for the half year were £69,862, against £54,782 for the corresponding period, showing an increase of £15,080. This is made up as follows:—Expenses in connection with repairs to the cables show an increase of £8,055. As you are aware, this is always a fluctuating item. Salaries and wages at foreign stations show an addition of £3,360. These are principally due to the new China stations. Rent, taxes, &c., also show from the same cause an increase of £1,130, and the maintenance of land line expenses show an increase of £1,540. These, with one or two other items, make up the increase of £15,080. The net revenue for the half year amounted to £117,720, against £110,755 for the corresponding period of 1882, showing an increase of £6,965. An interim dividend at the rate of 5 per cent. per annum has been paid for the past half year, and it is proposed to distribute another dividend at the same rate on the 24th inst., together with a bonus of 3s. a share, which, with the previous payments for the first half of the year, will make a total distribution of 7 per cent. for the year 1883, against 6½ per cent. for 1882, when our share capital was half a million less than it is at present. When I last had the pleasure of addressing you, I referred to the prosperous state of the Company, and said that I thought if the prosperity continued I might almost promise that some addition would be made to the dividends. You will observe that we have fulfilled our promise, and have still to carry to our reserve fund a very considerable amount. I believe the policy which we have adopted of paying a 5 per cent. dividend and dealing with anything over 5 per cent. in the way of bonus will be the most satisfactory course to the shareholders. I hope it will always be in the right direction, and every year gives us greater confidence in the class of property we are now dealing with. We have, as you are aware, been passing through a time of very bad trade generally, and when the cycle of good trade comes, as I believe it must, there is no institution that will derive greater benefit from it than the telegraph systems of the world. You are now, as I have said, receiving an additional dividend, and I think the fact that we are in a position of being able to pay 7 per cent. is one which we have all of us good reason to congratulate one another upon. When I last addressed you I referred to negotiations which were then going on with the French Government for connecting Tonquin with the Company's system. I did not go into details. I was asked to give some information, but I said it was not well to deal with an unsettled question. The bargain, however, has since been made. We get £10,600 a year from the French Government for twenty years. The cable has been laid, and is now working successfully. I was in Paris last week, and had the pleasure of seeing the Minister of Marine and the Colonial Secretary, and they expressed themselves highly pleased with the way the work had been done, and with the manner in which the cable was being worked. They told me that they were getting telegrams from Tonquin in the course of a couple of hours, whereas before the telegraph system was inaugurated it took many days to receive communications. I may mention that we are utilising the cable from Saigon to Tonquin as an alternative line between Saigon and Hong Kong, by carrying on the system from Tonquin to Hong Kong by means of cable from our stock at Singapore. We shall eventually require to lay another cable from Singapore to Saigon, and in that way we shall have duplicated our system. As I have stated on more than one occasion, now that commerce is so much dependent on telegraphy, and as so many important operations of the country are conducted by the telegraph instead of by letter (letters now being principally used for registering the transactions), I say again that it is impossible to have any system of telegraphy perfect, so as to secure the entire confidence of the mercantile community, unless our systems are duplicated. We have duplicated our system so far without any permanent addition to our capital, and I hope we shall, with a very moderate addition to it, be able to duplicate the whole of our system, and maintain our dividends, making their maintenance more certain from the fact of our having two lines instead of only one. We have also carried out another operation since I last had the pleasure of addressing you—that is the convention we have made with the Portuguese Government for connecting Macao with our system at Hong Kong. That has been talked of for the last twelve years, but the war movement in China lately induced those interested in this Company to communicate at once with Portugal, and the result has been perhaps one of the quickest operations ever done in that country, namely, that in the last three or four months we have secured a concession giving us a subsidy of £500 a year, with the traffic in addition, which I hope will prove fairly satisfactory. We intend that the cable laid shall be taken out of our store at Hong Kong, which for the short distance involved will suit the purpose exceedingly well. Now as to the Hong Kong and Canton line. I think when I last addressed you we had some little trouble with the Chinese. They are a peculiar people, but when fairly dealt with will generally conform to what can be shown is for their interest. The line is now connected with our system, and as it is opened and working satisfactorily our relations with the Chinese are becoming more friendly every day. There is also another question that affects us a little—namely, the line recently opened between Bangkok and Tavoy, which we thought might create competition. I had always very great doubts of the line ever being made to work satisfactorily, and those doubts have been so far confirmed. Since the line was opened two months ago it has broken down three or four times, and we have just received a telegram from the Director-General of India to this effect:—"Director-General India wires Bangkok that he is to close Tavoy line till after next season's work. Cause mortality among staff. Difficulty maintain during rains." I think, therefore, that we have very little to fear from that system. I also mentioned when I last addressed you that the Sunda Straits cable belonging to the Java Government had been destroyed by earthquake. During the last two months a fresh cable has been laid, and is now in good working condition. In regard to our cables generally I may say that they are all in satisfactory working order at the present moment. Our repairing ships have been steadily employed, but the result has been that we have had no interruption to cause any loss of traffic, and that has arisen in a great measure from the system we have adopted of duplicating whenever we could do so without any serious inconvenience or cost. We have taken up a good deal of the cable which was exposed to the teredo. We have replaced those lines to the extent of over 1,000 miles, and we find at last that we have really beaten the teredo. I hope there will be no other insect to cause similar interruptions. I may conclude by saying that during the past year we have added to our system 1,685 knots, of which 894 are brass-ribboned, making the total length of the Company's system 12,100 knots of cable, and I think I may say without any hesitation that we have got a system which we can control. If an interruption takes place in any part of our system we can mend it, and in a very short time; and I think this is the first time that I have been able to say emphatically and distinctly that I believe submarine telegraphy to be a sound and safe property. With these remarks, I beg to move:—"That the report and accounts of the directors now submitted be received and adopted, and that a dividend be now declared of 2s. 6d. per share, together with a bonus of 3s. a share, both free of income tax, payable on the 24th inst., making, with the previous distributions, a total payment of 7 per cent. for the year 1883."

The Most Hon. the Marquis of TWEEDDALE: I beg to second that.

The CHAIRMAN: Now, gentlemen, if there is any shareholder present who wishes to ask any question, I shall only be too happy to answer him.

Mr. MATTHEWS: There is one question I should like to ask. Our traffic receipts represent us as having received £215,958 in the course of the last six months, whereas our receipts by messages are only £198,428. I should like to know the reason of that difference.

The CHAIRMAN: You are aware that there are several lines subsidised, and that the monthly statements which we publish are to some extent an estimate. The figures include all the subsidies except the one given by Australia for duplicating the cables. But you have the full and complete statement in these accounts. He then put the motion in the usual way and declared it carried unanimously. Continuing, he moved the re-election of Sir James Anderson.

Sir THOMAS FAIRBAIRN, Bart., seconded the motion.

The CHAIRMAN put it, and declared it carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. GEORGE GARDEN NICOL, Mr. Francis Augustus Bevan was re-elected to his seat at the Board.

Mr. WALKER then moved, and Mr. MARCUS seconded, the re-election of Mr. Henry Dever and Messrs. Quilter, Ball, and Co., as auditors for the ensuing year, at a remuneration of £100 each.

The CHAIRMAN put the motion and declared it carried unanimously, adding that that closed the business of the meeting.

A vote of thanks was then unanimously passed to the chairman and directors for their services for the half year.

Digitized by Google

The CHAIRMAN: On behalf of my co-directors and myself I may say it always affords us great pleasure to meet the shareholders, more particularly when we can show that there is some little progress in the concern. You may depend upon it that we shall endeavour to continue to administer your affairs in a way that will command your approval.

The meeting then closed.

## THE BRAZILIAN SUBMARINE TELEGRAPH COMPANY (LIMITED).

The twenty-first ordinary general meeting of the Brazilian Submarine Telegraph Company (Limited) was held at the Cannon-street Hotel, London, on the 23rd inst., Sir James Anderson (the vice-chairman) presiding.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the last meeting, which were confirmed and signed by the chairman as correct.

The report of the directors was taken as read.

The CHAIRMAN: Gentlemen, before moving the adoption of the report I will, as usual at these meetings, make a few remarks. I am very sorry, of course, that our worthy chairman is absent through a prolonged illness, but we are in hopes that he will be back at our meetings very soon again. The principal item in the report is one which we must regret. We have to record the loss of £37,000 in the revenue for the last half year, mainly owing, however, to 74 days' interruption of our long cable from St. Vincent to Pernambuco. £6,000 of that, however, is owing to opposition and competition in a very small degree of the West Coast Route, and in a larger degree owing to a reduction of the tariff. The traffic has not yet had time to recoup that loss which always follows a reduction of tariff. As to the loss by the interruption of the line, I think I can very honestly congratulate the shareholders upon the result of that large repair; the cable was repaired in very deep water in a part of the ocean where we had every reason to apprehend considerable difficulties both from currents and unknown depths. For my own part I look upon these repairs, made by the Telegraph Construction Company with an experienced staff, with unfeigned admiration. It is quite remarkable, though I am somewhat used to it, to find how ably they go out in those great depths and pick up cables. One thing is quite clear I think, from the experience that we have had for the last 17 years, and that is that we shall always have interruption to the cables. I think it is confirmed now that wherever there is rocky or uneven ground, great inequalities or small inequalities, in time the cables break, and as far as I have seen there has never been a repair effected yet till they managed to get off the rough ground and find the cable lying in a smooth bottom. Therefore, we never quite know how much cable is required before we can bridge over or get round the bottom of the ocean where it is rocky and unequal. It is most satisfactory to me, as it must be to all of you, to know that the cable we recovered, notwithstanding its having been immersed ten years, was in thoroughly good condition. That to my mind is one of the most satisfactory evidences that we can have of the value of our property—that after ten years' submersion we can go and recover it, there being only the trouble of finding out how to get off the rough ground and how to avoid it in other repairs. It is impossible, as far as modern science has taught us, to find how to sound the ocean so thoroughly as to lay a cable entirely on a smooth bottom. I have known an inequality of two miles of depth occurring in half a mile of distance. Only this morning the captain of one of our ships told me that he went to repair a cable, where he expected, as the nature of the spot had been well established by innumerable soundings, to find only 45 fathoms, and he found 300 fathoms. Another captain told me that under the bow of his ship he had 80 or 90 fathoms, whereas he had 260 fathoms under the stern. With such inequalities as that you will understand that we must have expensive repairs and great difficulties in repairing cables in certain places. Fortunately we have had in this Company a very long immunity from repairs and accidents, which has enabled us to amass a very substantial reserve fund. With this reserve fund we shall be able to pay for an entirely new cable, and also the cost of the last repairs, £28,000, with the exception of an amount that we shall have to raise in debentures of from £150,000 to £200,000—less than £200,000 certainly. I think that is a position that we may congratulate ourselves upon—that after ter years we shall have a duplicate system without increasing the capital except by a very small amount. With the cable duplicated we can fairly look forward to avoiding such loss of revenue as I began by referring to. Therefore with a duplicate system we are altogether in a better position. I understand also that our neighbours, the Western and Brazilian Company, are about to lay a very large section of new cable in the parts of their system most liable to interruption. I think that we are justified in assuming that with our system duplicated and the Western and Brazilian Company's cable put in first-class order we should avoid those interruptions which not only lose revenue, but which from our experience we know interfere with the progress of the traffic. We know that telegraphy will never grow where the service is halting and unreliable. Merchants will not telegraph keenly unless they feel that they can rely on a well maintained and efficient system. With this system in that condition I hope (and I think that our statistics show it) that we may fairly anticipate paying off our debentures, laying by a fair reserve fund, and continuing a fair dividend of 5 or 6 per cent. The managing director says 6 per cent. That is, looking at it at the present moment, and with our new system and avoiding interruptions, I have for my part very little doubt about it. These are all the remarks that occur to me at present to make, but if any gentleman has any question to ask before I submit the motion to the meeting I shall be happy to reply to him.

In reply to Dr. James Weaver, the CHAIRMAN repeated that the £6,000 loss to which he had referred had been owing to competition and the lowering of the tariff, and that time was required to make good the loss of the revenue caused by the reduction of the tariff. The competition to which he had alluded was that of the West Coast Route, which company had lowered its tariff to oppose this Company, trying to get the traffic from the River Plate round by Valparaiso and Galveston. This, however, was not doing the Brazilian Submarine Company any substantial harm. There was no new competition contemplated that he knew of, and the West Coast Route had only opposed them by lowering the tariff in the last twelve months. In further reply to Mr. Griffith, the chairman added that the directors at their next Board meeting would consider whether the debentures should be issued in the form of stock or as debentures payable to bearer. He concluded by moving the adoption of the report and accounts to the 31st December last.

Sir THOS. FAIRBAIRN, Bart., seconded the motion, which was carried unanimously.

On the motion of Mr. GRIFFITH, seconded by Dr. WEAVER, a vote of thanks was passed to the chairman and the directors.

The CHAIRMAN: My colleagues and myself thank you for your confidence, and I hope we shall continue to deserve it.

## MONTE VIDEAN AND BRAZILIAN TELEGRAPH COMPANY (LIMITED).

The ordinary general meeting of this Company was held on the 21st instant, at the offices, 2, Tokenhouse-buildings, King's Arms-yard, Moorgate-street, Sir Thomas Gore Browne, K.C.M.G., in the chair.

The report of the directors for the year ended December 31 last stated that the Company's percentage of the gross earnings of the Western and Brazilian Company had amounted for the year to £2,240, being a reduction of £529 as compared with the preceding year. After setting aside £500 for redemption of mortgages, and providing for all charges and debenture interest accrued during the year, there remained a balance of £457, out of which it was proposed to pay a dividend of 1s. a share (10s. per cent.), and to carry forward a balance of £41.

The CHAIRMAN formally moved the adoption of the report.

Mr. CHARLES CAMERON, M.P., in seconding the motion, stated that the revenue of the Company entirely depended on the percentage of earnings of the Western and Brazilian Company, whose income had suffered from a long interruption to the cable, lasting from September 22 to December 4. The directors regretted to inform the shareholders that another interruption had occurred early this year, which, though not of long duration, would still occasion considerable loss. Another cause of the falling off in the receipts had been the competition of the Brazilian Government land lines, which had led to the reduction of the tariff of the Western and Brazilian Company to the tariff of the land lines as from September last. This would further affect this Company's percentage of the receipts.

The report was adopted, and resolutions were afterwards passed declaring the dividend recommended, and re-electing the retiring director and auditor.

## REUTER'S TELEGRAM COMPANY (LIMITED).

The twentieth ordinary general meeting of shareholders was held on Wednesday at the offices of the Company, 24, Old Jewry. In the absence, through indisposition, of the chairman of the Company, Colonel James Holland, the chair was occupied by Admiral the Right Hon. Sir John C. D. Hay, Bart., M.P.

The notice calling the meeting was read by Mr. Fred. J. Griffiths, the secretary, and the report and accounts were taken as read.

The CHAIRMAN, having expressed his regret at the absence of Colonel Holland, and his hope that he would shortly resume his duties at the Board, went on to say: Gentlemen, I will now proceed to move the adoption of the report and balance-sheet. I have nothing to say with regard to the report, which speaks for itself; but with respect to the balance-sheet I should like to make one or two observations. You will observe that the sundry creditors show a decrease of £5,657, owing to the loan of £5,500 from the bank having been paid off, and the smaller sums due to telegraph companies at the end of 1883 compared with 1882. On the other side, with regard to sundry debtors I should like to give you this information: This account has diminished by nearly £2,000, and the explanation of that is that the balances in the hands of agents and other persons have diminished to that extent. The reserve fund is increased to £8,049 9s. being the usual addition of the rental of 24, Old Jewry, and it will, as explained in the body of the report, be further augmented to £10,000. As to the profit and loss account, in the current expenses you will see there is hardly any variation; but the "telegrams and agencies" have decreased nearly £7,000, but about £5.000 of this is owing, or chiefly owing, to the cessation of the very exceptional expenditure through the Egyptian war, and £2,000 is due to the change in keeping the accounts. The subscriptions and commissions have apparently, but not really, diminished by £2,000. In regard to the reserve fund, the chief reason for increasing it is to furnish resources in case of need, and to meet exceptional expenditure. At present there is no special demand upon it. The Company's business is everywhere in a sound condition, although during the past three months Egyptian affairs have again entailed some heavy expenses. These, gentlemen, are the only remarks which the chairman would have offered the meeting, or which it occurs to me to offer; but if any gentlemen present desire to ask any question I shall be happy to answer it, or my friend Baron de Reuter will supplement any infor-

Digitized by Google

mation in which I find myself wanting. I beg to move the adoption of the report and accounts.

Baron DE REUTER seconded the motion, which was put and carried without discussion.

Mr. J. S. STOFFORD: I have pleasure in moving the re-election, as a director, of our chairman, Colonel James Holland. You have just heard from our chairman that Colonel Holland is unwell, and has been kept from our meeting for the first time in twenty years. I need not say how much we esteem him as chairman, and how efficient a chairman he is. I am sure you will gladly see him again here, and therefore I have great pleasure in proposing his re-election.

Baron DE REUTER seconded the motion, which was carried.

The auditors, Messrs. Quilter, Ball, Crosbie, Glegg, and Welton were re-elected.

A SHAREHOLDER proposed a cordial vote of thanks to the chairman, directors, and also to Mr. Griffiths, the secretary, for the careful and able manner in which the business of the Company had been conducted during the past year.

The resolution was seconded and carried.

The CHAIRMAN: Gentlemen, on behalf of my absent friend, Colonel Holland, and on behalf of the Board and myself, I beg to return you our best acknowledgments for the vote of thanks which you have passed to us, and we shall be, I may say, as constant in our attendance, and perhaps it is one of the advantages which result from having a very small Board that we are, I may say, almost always here. It is necessary for almost all of us to be present to form a quorum. There have been no changes on the Board for twenty years, and we attend constantly in the board room, and you have expressed an opinion that our attendance has been useful. I can say on Colonel Holland's behalf, and our own as well, that we will do our best in the future to attend not only in the board room, but also to the business of the Company.

The proceedings then terminated.

## THE ELECTRICAL POWER STORAGE COMPANY (LIMITED).

The annual general meeting of this Company was held on Wednesday at the Cannon-street Hotel, Sir Daniel Cooper, Bart., in the chair.

Mr. H. DELL (the secretary) read the notice convening the meeting, and the report of the directors was taken as read.

The CHAIRMAN stated that since the last annual meeting the Company had not prospered. The balance-sheet showed a considerable loss on the year's working, and a heavy expenditure in relation to maintenance, upkeep of patents, and also in connection with negotiations for their sale. He placed in contrast the position of the electrical world when the Company was formed and at the present time. The Company had foreign patents which they hoped to realise favourably, more particularly in America, as Mr. Courtenay, one of the directors, would explain, he having just returned from a lengthened stay there. As to France the position was, as the Board were advised, a secure one for the Company. He gave short particulars of some of the complicated negotiations which had taken place, the difficulties which had to be overcome, and the means by which this was achieved both in Paris and Brussels. Another unpleasant matter was the action of a portion of the shareholders of the Indian and Oriental Company. The Company always had been most desirous to foster and support that company, and to deal with it more than liberally. In that spirit the patent for the cone type battery was offered to the Indian Company without payment, and the directors accepted the proposal with acknowledgments of the liberal treatment they were receiving in the matter of the accounts between the companies for goods supplied also. Notwithstanding this a small section of the Indian Company's shareholders adopted a course which did not only that company but this one an immense amount of injury. All accounts, however, were adjusted between them, and the last £5,000 cash due from the Indian Company had been paid. The Australasian Company sought to rescind a contract made by this Company with Sir Julius Vogel for an option to purchase this Company's patents. The verdict went against them, and on appeal the Lords Justices decided against them, and no further trouble need be apprehended on that score. In Germany the German Edison Company have made a contract, which is, however, purely provisional, and gives them the right to a sole licence for Germany at a fixed royalty, with a lump sum down in anticipation of the first royalties. They are now working our accumulators in an installation, and in August they have to announce their decision. This was one of the fruits of the Vienna Exhibition, and might recoup some of the outlay there. The Company exhibited at Vienna rather reluctantly, but had to face two important considerations—the first, that coming after the Paris Exhibition they had never displayed on the Continent; and the second, that the Company's agent on the Continent maintained it was useless hoping to effect a patent sale there unless they did exhibit. If the immediate result had not been to bring profit it had certainly brought reputation, for the tests made by the commission were thoroughly satisfactory, and bore out the claims made as to efficiency. In the two countries of Europe where there exists no patent protection, viz., Switzerland and Holland, licence arrangements had been entered into with the two leading electrical firms, they being respectively M. Emil Bürgin, the inventor of the well-known Bürgin dynamo, and the Netherlands Electrical Company. Referring to the installations made by the Company, it was explained these were of two classes—those that are paid for outright on completion, which are very satisfactory, and of which the Company wanted to get as many as possible, and then those which are really lighting contracts, where the Company find all the plant and materials and the customer only pays a rent. The experience of the Board with regard to the latter installations does not encourage them to go on with this kind of business, as the cost in material and labour in putting up an installation is very great; and if the person for whom it is made fancies he can do better himself or through trade rivals, he gives notice that he will not continue the installation unless on his own terms, which are generally far under cost price. The Company then finds itself in a dilemma of either having to make a heavy annual loss or a heavy loss at once amounting to nearly the full cost of the installation. The Grand Hotel was instanced as a case in point. The contract was made at a time when the Company required to have a show installation, and the electrical world were committing suicide by talking of "under gas rates" for electric lighting. The terms made were thought to be good, and doubtless with more convenient and economic motive power would have been satisfactory. But gas-engines of large power kept very constantly at work give much trouble and cost a great deal. The proprietors of the hotel, Messrs. Gordon and Co., saw all this, and hoped to find steam motive power outside, and for a time they were negotiating with the Company to light their enormous new hotel, the Métropole, also, when it was finished. But they could not manage what they hoped as to steam power, and when they asked for a price for the future for the Grand Hotel alone a profitable one to the Company was quoted. But Messrs. Gordon and Co. thought they could do better. The Company preferred to make a large loss at once instead of an annual one, with the certainty of a large one whenever the contract might terminate; and so the installation was given up by the Company. Messrs. Gordon and Co., however, were perfectly satisfied with the Company and its work, and had written a cordial letter to say so. In theatre lighting the accumulators were doing very well indeed, as any one might see either at the Gaiety or Prince's Theatres in London, and others were expected. But the installation which they looked at with most satisfaction was the Bank of England. They had begun there cautiously, with one principal part of the building as a test, and he was proud that they entrusted it to their Company, because the Bank made careful investigation and found theirs to be the only system fulfilling the Bank's stringent requirements. The installation has been running without a hitch; every body is pleased. The Bank had taken it over and paid for it, and they looked forward to make an installation for them on a far larger scale for next winter. Another small matter in itself was the business commencing in the temporary lighting of ball rooms, evening parties, lectures, &c. It pays well in itself, but is of still greater use in bringing the value of electric light well before the right people. Railway train lighting is just being brought into use, and if it proves as successful as those who have invested their money in it anticipate, it would be a great help to the Company. The system adopted is the Stroudley-Houghton, in which accumulators are used. It seems to be reliable and economical, and if it once takes the business will become very extensive. As regards the employment of accumulators for motive power, the success on land had been moderate, but on water it had been great. Thanks to the very spirited co-operation of the eminent shipbuilders, Messrs. Yarrow and Co., the little boat, the "Electricity," was followed up by an elegant launch of good diminsions, which formed a leading attraction at the Vienna Exhibition, and before its departure was seen several times on the Thames. It worked admirably, and met with great praise on all hands. There had been, however, great progress on the Continent in land locomotion, the benefit of which must inevitably accrue to this Company. Referring to the announcement with regard to the cone type of battery, it need only be said that the Company has now acquired this free from any personal ties or incumbrances. This has only lately been achieved, and the Company are consequently only now undertaking experiments on their own account. It can be said, however, that as regards this type, and also the clamp type referred to in the report, as designed by Mr. Sellon, there was reason to expect they would do useful work, and help to develop, each in its way, the business of the Company. After referring to the accounts which accompanied the report, he gave an explanation of the proposed reduction of the capital, the effect of which would be to give one £1 share for two £2 shares, and it was pointed out that as the capital was fully paid, it really was immaterial to the shareholders what the nominal amount of each share was. It has been said that by reducing the capital in the way proposed that each shareholder has had twenty shillings taken away from him and five shillings given in return, and therefore the patents have been reduced by the like amount. I beg to differ from this statement. A sovereign with 20 marked on it and a 5s. piece with 5 on it are fixed and known quantities, but a share certificate with 20 or 5 marked on it is an unknown quantity, and whether the certificates be marked 20 or 5 will make no difference in realising the patents, which may, when disposed of in detail or in block, give an amount to allow 50s. for each share, or, if things turn out badly, 6d., or nothing at all. In view of putting the expenditure on the most economical basis, and to suit the means and reduced capital of the Company, the directors had carried out sweeping reductions at the works, and proposed judiciously still further to do so. Mr. Bullivant and Mr. Volckmar, the managing director, had resigned, and it was not proposed to fill up their seats, but Mr. Courtenay had agreed to act as managing director, and other consequential arrangements as to the staff would be made. He entertained a strong view that it might be to the interest of the Company to introduce fresh blood at the Board, and to permit this to be done Colonel Steuart and Mr. Ladd had very kindly stated their willingness to retire if two gentlemen could be found who in the opinion of the shareholders and the Board would strengthen the directorate. The almost total failure of the customers to whom the Company had a right to look for business left no course open for it but to enter into general electrical work, and henceforth they would be prepared to tender for the erection of complete installations in all parts of the country, and for the production of any electrical machinery for

Digitized by Google

which they could obtain profitable orders. The works of the Company were admirably suited for the purpose, and were capable of doing a large amount of business. One thing they could say with great satisfaction was that the workmanship of all the Company's goods, whether accumulators or otherwise, stood in the highest repute, and it was intended to maintain that character. In conclusion, the Chairman moved the adoption of the report.

Mr. J. S. SELLON, in seconding the motion, referred to the various difficulties the Company had passed through, but said they need have no fear with respect to competition from primary or secondary batteries. With respect to the present position of accumulators, he must say that they had attained a degree of electrical efficiency which left but very little room for improvement. From 90 to 95 per cent. of the energy acquired from the dynamo machine could be drawn off, of which at least 80 per cent. was available for effective work, the residuum remaining in the batteries towards the next charge. The directors had unabated confidence in the future of the business of the Company.

Mr. COURTENAY said: You were made aware, gentlemen, by the chairman's speech of last year of the position of the Company in America at that date. In June last I went out again to supervise the Company's interests and to conduct the litigation referred to by the chairman as then pending in New York, and to consult with the Company's patent lawyer at Washington in the heavy contest which is going on in the Patent Office, and which involves the principal patents of the Company in the United States of America. You know that the patent procedure in America is quite different to what it is in this country. We are protecting, on the one hand, our issued patents, among which are some of the Faure patents, the Sellon patents, and others, against piratical attacks by numerous inventors who are endeavouring to get patents for inventions which we contend are already covered by the Company's patents, while, on the other hand, we are making applications for patents which have for their object improvements in the secondary batteries manufactured under the patents we have already obtained. The American patent for Mr. Gustave Philippart's cone battery was obtained during my stay in the States, and is now owned by this Company. In a word, we are building up a valuable series of patents in the United States and covering all important points. I say we, because, as you are aware, this Company, though it has transferred its American patents to an American corporation (the Electrical Accumulator Company of New York), receiving fully paid stock in exchange, holds the controlling interest in that corporation. Thus much, then, for that branch of our work which deals with the patent litigation in the Patent Office at Washington. Some of you may not know that under the American Patent Office system these contests often last for years. I cannot leave this subject without adding my testimony to the skill and watchful care bestowed upon the patent suits at Washington by the gentleman who is defending the patents there—I mean Mr. Anthony Pollok. I now come to a delicate topic, namely, the pending litigation in New York; I cannot without injury to the Company's interests give full details upon this head. At the meeting of the Company last spring, during my absence, a report of explanations made to the shareholders was sent to New York, and was there made use of in court to our detriment. I do not propose, with your permission, on this occasion to furnish our adversaries with any materials that can be of service to them. You will remember at that meeting it was stated that we were in litigation with the Light and Force Company of New York, in whom the Faure patent for America was originally vested, and that we claimed 49,000 shares of stock of the nominal value of 4,900,000 dollars. I stopped that litigation, and, without going into further details, I can assure you that the Light and Force Company of New York, which once was hostile, is now a friendly corporation. It has its abode at the same office as is occupied by the Electrical Accumulator Company of New York, at 78 and 80, Broadway, where also our legal advisers, Messrs. Parrish and Pendleton, who so well represent this Company, have their office. There is an installation there of our accumulators which is quite creditable considering the many difficulties. The further litigation which is still proceeding is against several sub-companies and individuals for stock and interests in the Faure patent, which they claim to have become entitled to through the Light and Force Company. These claims are most extortionate, and must be resisted. They are the outcome of numerous and complicated transactions entered into before my first visit to the States on the Company's business, and during the period when the Light and Force Company was hostile. A trial lasting for several days has taken place, but the judgment has not as yet been given. We have been and are ready to negotiate a settlement on fair and reasonable terms, but we shall not make any compromise that is not just and equitable. The expenditure in America is chiefly made up of the outlays in connection with the above proceedings. The third point in connection with the American business is how best to deal with our interests in that country, which are practically represented by the stock we hold in the Electrical Accumulator Company of New York. The nominal capital of that company is five million dollars, and I have already said we hold the controlling interest. Negotiations were in progress to bring into the business some of the most substantial and shrewd business men in the United States, with a considerable amount of American capital, and these will be continued, but serious injury was done by the persistent efforts made to impair our title to the Faure patents, and by notices published in the New York papers and other methods, while the published reports of meetings in this country of people interested in our system of secondary batteries were most damaging. Some work in the way of installations has been done there, and I hope soon to hear of more. The complications I have mentioned have seriously checked the development of the business, but one of the offshoots of the Light and Force Company, commonly known as the Baltimore Company, had nearly completed a new factory when I left. There is great interest taken in secondary batteries in the United States, and there is no question as to the immense field for the business of the Company. I shall now conclude my remarks on the American business with an expression of my opinion that if vigorously and judiciously followed up it will prove a very profitable investment. On my return to this country a few weeks ago I learned that serious complications had arisen in connection with the contract for the sale of the Company's patents to the French Electrical Power Storage Company. You will have observed the note appended to this item in the Patent Sales account. The bankruptcy of the French Storage Company has been declared in Paris, and it is now in the hands of a syndic—an official who in France practically corresponds to a liquidator in this country. The French Storage Company has failed to carry out its contract with us, and the patents therefore revert to this Company. I was asked by the directors to look into this matter, and have in consequence paid several visits to Paris to consult with our legal advisers in France. A brief report from our counsel has been received. We are now in communication through them with the syndic, and at the moment it is not politic to say more upon that subject.

The report was adopted after a short discussion, and the resolutions referred to by the chairman for the reduction of the capital having been adopted,

A vote of thanks to the chairman and directors terminated the proceedings.

## THE RAILWAY AND ELECTRIC APPLIANCES COMPANY (LIMITED).

The ordinary meeting of this Company was held at the Cannon-street Hotel, on the 18th inst., under the presidency of Colonel R. Raynsford Jackson.

The SECRETARY (Mr. W. Shepherd) read the notice convening the meeting.

The CHAIRMAN stated that the Duke of Manchester (the chairman of the Company) had intended to go abroad on the 6th inst., and had announced to his colleagues that he did not intend to take part in the business of that meeting. He (Colonel Jackson) had therefore been invited by his co-directors to take the chair. He would have said very little indeed but for the opposition with which the directors were threatened, to the character of which he would afterwards refer. With regard to the report of the directors, he regretted that it contained the announcement of a serious loss by the Company during the eighteen months which terminated on the 31st December last. That loss amounted to over £14,000; but it might be some consolation to them, however little, to know that other companies similarly engaged had also experienced grave losses.

A SHAREHOLDER: They are not similarly engaged.

A SHAREHOLDER: We have come to hear about this Company, not about other companies.

The CHAIRMAN, continuing, stated that no interruption would prevent him from making the statement he intended to lay before the shareholders; and he maintained that the losses of the Company had been paralleled or exceeded by those of other companies in similar lines of business. Fault had been found with the directors for being reticent, and not giving fair accounts to the shareholders, but how could such a statement be justly made when they had not only given a balance-sheet and manufacturing account, but also a profit and loss account? With regard to the policy of the directors in endeavouring to secure for the Company freedom from a very heavy charge upon its assets, he wished to state the operation of the compromise which the directors favoured, and which he trusted the shareholders would carry out. The capital of the Company consisted of 91,732 ordinary shares and 73,500 fully paid up shares. The result of the compromise was to reduce the capital of the Company in that element which pressed most upon its interests by 50,050 shares, so that the capital of the Company would be reduced from £170,232 to £135,822. Looking at the position of the Company as it was affected by the compromise, taking into consideration the capital actually called up, this was the state of affairs: Whereas the capital was before £170,000, it would be £120,000; but if they took the money called up upon the shares at £57,322, and the fully paid shares remaining, they would have a capital of £85,772 against £135,822. The capital entitled to claim on the profits or on the assets of the Company in the event of its liquidation was thus very considerably reduced. The 50,050 fully paid preference shares, which they got rid of by the compromise, would be first claimants on the assets of the Company, and would be entitled to take, before the ordinary shareholders took anything, £18,768, which would more than absorb the free capital of the Company. It was therefore, he said, enormously to the interest of the Company that the compromise should be carried out. While on this subject he wished to refer to the circulars and pamphlet which had been issued by Mr. Williams. They contained a good deal of what was almost vituperative, and at all events very abusive, but he would not waste the time of the shareholders and his own time by going into that portion of them, although he would be ready to answer any question concerning what was stated. The balance-sheet prepared by Mr. Williams he, however, desired to draw their attention to. It was an amazing document, in which Mr. Williams had tried to show the advantage of getting rid of the compromise. Mr. Williams could not, as he had claimed, get £29,000 out of the Williams Company, as that company only had £8,000 out of its capital to develop its business, nor could he get £22,000 out of the National Electric Company, for it had only between £8,000 and £9,000 of capital. Mr. Williams had also said that if they got rid of the compromise the Company could get out of certain gentlemen £24,000, making that statement, however, on the presumption that the courts

Digitized by Google

would settle everything in favour of the view taken by Mr. Williams. Mr. Williams also claimed the value of the Williams patents to be £24,000, and stated that some of his (Col. Jackson's) friends had offered that amount for them. He could only say that he knew of no such offer. He could, he believed, undertake to obtain for Mr. Williams not only the patents which the Company held through the amount paid to him (Mr. Williams), but the patents which were held by the Williams Company, in exchange for the 17,500 fully paid shares which Mr. Williams held in this Company. He also wished to ask how Mr. Williams was going, first, to get £29,000 from the Williams Company, and then retain the property secured for the Williams Company as an asset of this Company? If the contract were rescinded on the one side, it must be rescinded on both sides. Looking at Mr. Williams's statement as a whole, he thought they might regard it as utterly worthless. Again, where Mr. Williams had endeavoured to show what would be the effect of agreeing to the terms of the compromise, he had put on the debit side £5,000 for legal charges, but on the other side, where all that he could possibly obtain could only be through costly litigation, he had put down nothing for legal expenses. He thought the other side should not be forgotten. They might go into costly litigation and fail, and if they failed they would lose all the assets to which Mr. Williams had referred, and be landed in ruinous costs besides. He thought it would be suicidal to set aside the compromise made by the directors in the interests of the shareholders, but he might tell their opponents that if the attempt were made it would fail, because the proxies held by the directors—their voting power—was so considerable that they could check the attempt to control the affairs of the Company to its detriment. Mr. Williams had, he said, dealt very freely with motives, and that being so, he would read them a letter written by Mr. Williams on the 12th inst. in contemplation of that meeting. Having read the letter, he stated that it thus appeared that Mr. Williams had the strongest desire to sell his interest, and one of the motives which he had put before those to whom he had applied was that it would be to their interest probably to get rid of his opposition at the meeting. He therefore thought that Mr. Williams must no longer pose as working hard for the benefit of the Company alone, and without any selfish motives. With regard to the working of the Company the expenditure had been reduced. The salaries at the Polmadie works had been reduced from £2,232 a year to £630. The loss there was £502 a month during the eighteen months to December 31, but it had been £176 a month since. Mr. Williams had insinuated that this was because nothing was being done at the works, but they would see that that was untrue when he informed them that the goods sent out from the works averaged during the first period of eighteen months £253 a month, whereas during the last three months the goods sent out had averaged £444 a month. He trusted that beneficial results would accrue to the Company from these changes. The object which the directors had—reverting to the subject of the compromise—was to get rid of the incubus he had mentioned, and they desired in addition so to reduce the expenditure and increase the efficiency of the works as to turn a loss into a profit. His view was that they should give the works a further trial, and if they did not then succeed the shareholders would be called together and be consulted as to the policy which should be pursued. It would be much better for the dissentient shareholders, for their own interests and those of the Company, to leave their position as dissenting shareholders and to try and help in getting the Company through its difficulties. He concluded by moving the adoption of the report and accounts.

Lieut.-Colonel G. A. Elliot having seconded the motion, a long discussion followed.

Mr. J. S. Williams assured the shareholders that nothing but absolute necessity would have caused him to take up the disagreeable position which he had assumed in connection with the business of the Company. When, however, it was evident that their property was to be squandered by reckless management, or manipulated for the aggrandisement of a few individuals, and the rights and interests and property of the shareholders at large were ignored or were employed for increasing "illgotten lucre," it was necessary to speak out plainly. The circulars and pamphlet which he had issued to the shareholders exposed such a state of things as would constitute a grave charge against some of the persons in office who had guided and controlled the affairs of the Company from the commencement. All these statements were, he said, founded upon documentary evidence of a character which seemed to be unimpeachable. It was time that the shareholders were made aware that men who had occupied and who still occupied positions of trust in connection with the Company were concerned in its promotion, and received moneys for themselves unknown to the shareholders for transactions which they were nominally conducting on behalf of the shareholders. These same men had, he asserted, betrayed the true interests of the shareholders by concocting a programme to inveigle the shareholders into a compromise with themselves by which they hoped to extinguish their liability, and secure at an enormously reduced price the property which they had been the means of inducing the Company to purchase. Alluding to the promotion of the Company, he referred them to the full details which he had given on this subject in his pamphlet. Having drawn attention to the active steps which, he alleged, certain gentlemen connected with the directorate had taken in the promotion of the Company, he criticised its management, and observed that the balance sheet revealed disastrous results. The directors in their report offered no excuse or semblance of a reason for such ruinous results, but ejaculated a feeble complaint against the uncertainty and unsatisfactory nature of business in electric lighting. But why, he asked, had they not attempted to do business in the railway appliances which were the property of the Company? In these they held a monopoly, but no attempt had been made to turn this to good account. The shareholders would doubtless agree that the affairs of the Company were in more than an unfortunate position with directors who had divided interests. He then referred to the litigation which was pending, and having reminded them of the actions brought against the directors by certain shareholders for rescission of their contracts, he stated that the petition for liquidation of the Duke of Manchester and other directors was undoubtedly a mistake, and one which might have been avoided had the directors sought to take the shareholders into their confidence. He, however, saw no reason why they should refuse to support those who, like those directors, were honestly endeavouring to do their best against opponents such as they had to deal with. The Company was at present in this position: In consequence of the cross actions by the Duke of Manchester *v.* Smith and Smith *v.* the Duke of Manchester certain gentlemen connected with the Company had found an opportunity to come forward as intermediaries in order to arrange a compromise. The manner in which this was done on the 15th August last was, he said, illegal, and contrary to the Articles of Association of the Company, but in spite of this the attempt had been proceeded with. The terms of the compromise, moreover, were, from the shareholders' point of view, "simply scandalous." It was, he said, proposed to part with the railway appliances patents at a loss to the Company of more than £36,000, not to speak of the loss on the cash payments for works, patterns, &c., and with the electric appliances licence at a loss of £7,000, not to speak of the loss which had been entailed on the Company of at least £14,000 in endeavouring to work these appliances. If this were carried out the Company would, he maintained, have no foundation left for carrying on business. The Company would, he said, lose altogether about £55,000. The strongest argument would be supplied in favour of the dissentients' case, so that it was highly probable their subscriptions would have to be returned to them. Thus "crippled and stripped" how was the Company to survive? If, on the other hand, this wretched attempt were rejected the Company would retain the patents upon which solid business could be founded by proper management, and what remained of the capital might be saved. He confidently asked them to support the policy which he had sketched out, and to reject the attempt to inveigle them into a ruinous compromise. He concluded by moving an amendment to the effect that the report and balance-sheet be received "for examination, and referred to a committee of shareholders to consider the same, and report thereon to the shareholders."

Mr. Cummings seconded the amendment, and asked various questions, to which

The Chairman replied, stating that by the compromise they would get rid of the incubus he had referred to, and they would still be able to work under the Williams patents if they could obtain orders. The compromise stipulated that £50,000 or upwards of shares should be returned, and that Mr. Williams should have the option of entering into the same arrangement if he liked, taking back his patents, and giving up his 17,500 shares. When a compromise was entered into something had to to be given up on both sides, and that was the case in the present instance.

The Auditor (Mr. James Worley) replied in detail to certain questions on the accounts, stating that the item of £95,000 on the credit side of the balance-sheet included not only machinery and plant, but also the buildings. He thought it would be fair to assume that the total value of the works as a going concern would be £5,000 or £6,000, but the Company had taken credit only for the outlay on the buildings since they came into possession of the Company, amounting to £1,463.

The Chairman, in reply to Mr. Edmeston, stated that the business the Company was now doing, so far as the accounts of the last three months explained it, was still at a loss, but, as he had already intimated, at a very much reduced loss, and the directors would do all they could to convert it into a profit. As to the nature of the business, it was not electrical business, and up to now it had not been railway business—at all events, not business under Mr. Williams's patents, but miscellaneous business secured by the Company to employ its works. They had, however, received an order from the Wemyss Bay Railway Company for certain of the Williams appliances—the cross-over; but the importance of the fact of their obtaining the order lay in this—that the Wemyss Bay Company had before tried these appliances, and after a trial of some duration had come to the conclusion that it was expedient to adopt the system further. He was therefore in hopes that they might derive some advantage eventually out of Mr. Williams's inventions. Mr. Williams had complained that no effort had been made to secure orders for the appliances made according to his invention, but that was not the fact. The railway interest was especially conservative. It was very difficult to induce railway managers and railway directors to adopt new methods and new appliances, and although in Belgium Mr. Williams's appliances had been more used, the only company in this country that had yet even deigned to make a trial of Mr. Williams's inventions had been this one particular company. The accusation which that gentleman had made against the directors of turning their attention especially to electrical instead of railway appliances, therefore, he held, fell to the ground, as the Company could only execute such orders as it obtained. He afterwards explained his connection with other companies, referred to by Mr. Williams, and observed that, as to the proposed committee, as far as he was concerned, he treated with absolute contempt all the charges which had been made against him.

Mr. Cummings observed that some very serious charges had been made against Mr. Smith, and he thought that that gentleman should give some answer to them.

Mr. William Alexander Smith (Glasgow), in reply, stated that he had not intended to rise to answer a single word that Mr. Williams had stated either in his pamphlet or his circular, but after what Mr. Cummings had said he felt that he must alter the decision which he had previously come to. At some length Mr. Smith then replied in detail to Mr. Williams's charges against him, and indignantly repelled them. Notwithstanding all that had been said, however, he was as great a believer as ever in Mr. Williams's patents.

Mr. Hugh Watt explained the circumstances under which he had come to act with Mr. Williams, and assured the chairman that he had not

Digitized by Google

taken the prominent part in the opposition which Col. Jackson appeared to think.

The CHAIRMAN said he would accept Mr. Watt's explanation with pleasure. He afterwards stated that the directors would oppose the amendment. He then put the amendment to the meeting in the usual manner, and declared that "a large majority" had voted against it. He next put the original motion, and declared it carried.

A poll was then demanded.

The CHAIRMAN next moved the following resolution:—"That the special report of the directors as to the carrying into effect of the terms of the compromise of the litigation alluded to at the extraordinary general meeting held on August 15, 1883, and the deed of compromise now submitted be received, and the proceedings of the directors in reference thereto be approved."

Lieut.-Col. ELLIOT seconded the motion, which was declared carried by 13 to 8, on which a poll was again demanded.

On the motion of Sir G. R. PRESCOTT, Bart., seconded by Admiral Sir E. A. INGLEFIELD, COL. Jackson was re-elected a director by 14 to 6.

Mr. Worley was re-appointed auditor of the Company.

It was then decided to let the polls which had been demanded apply as for one motion only and to take the poll on the following day and on Monday last, the declaration of the result to be made on the next day.

An extraordinary meeting was then held, and

The CHAIRMAN proposed the following resolution:—"That the following article be added to the Articles of Association of the Company: Art. 33A.—The directors may accept from any member, on such terms and conditions as shall be agreed, a surrender of his shares or stock, or any part thereof."

Lieut.-Col. ELLIOT seconded the motion, which was declared carried on a show of hands, a poll, however, being again demanded.

A vote of thanks was then passed to the chairman, on the motion of Mr. CUMMINGS, seconded by Admiral INGLEFIELD.

---

At the adjourned meeting, held on Tuesday, at the offices, Lombard-street, Lieut.-Colonel Elliot presiding, the chairman announced that the votes for the adoption of the report numbered 57,917, and against it 25,216, showing a majority of 32,701. He had therefore to declare that the report was adopted. He then reminded them of the arrangement come to as to the questions to which the poll should apply, and stated that he had accordingly to state that the amendment was lost, that the directors' special report was adopted, and that Colonel Jackson was re-elected. With regard to the poll on the resolution submitted to the extraordinary meeting, the result showed that there was a majority in favour of the motion of 33,171 votes, but as a special resolution required to be confirmed by a vote of three-fourths of those present in person or by proxy, he had to announce that the resolution was not carried by the necessary majority. That fact was, however, practically of no consequence. The directors had been entrusted with 17,467 votes from ordinary shareholders, while the opposition had received 2,826, and the directors had also received 1,470 votes which arrived too late to be available for the poll.

---

## THE EASTERN ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of the above Company, adjourned from the 8th inst., was held at the Company's offices, 19, Great Winchester-street, E.C., on Tuesday last, Mr. Ernest Noel, M.P., in the chair. The notice convening the meeting and the minutes of the previous meeting having been read by the secretary (Mr. H. Cleland Heywood),

The CHAIRMAN said: Gentlemen, we have only one matter of business that we can carry out to-day. We can either dissolve this meeting or give effect to the object for which it was originally called, that is to say, the object of the meeting of the 5th of March. Since that time, as you are aware, Mr. Bull, one of our shareholders, has returned from India, and he is persuaded that there is a business to be done there, but more especially in Bombay. I so far agree with Mr. Bull, that I have not despaired of electric lighting, believing that there will eventually be a business in Bombay. But our funds are exhausted. We have attempted to get capital from our shareholders. Of course the outside world would certainly never come in, but we have endeavoured to raise capital among our shareholders, and have met with absolutely no response. They were not prepared to advance more money for a scheme which, in the present condition of electric lighting, did not seem sufficiently hopeful. That being the case, I still think, and the Board are agreed with me in thinking, that it will be for the advantage of the shareholders that we should go into voluntary liquidation. Under voluntary liquidation it will be possible to do one of two things. It will be possible either to sell the Bombay installation and business as they now stand for a definite sum which, after clearing the liabilities of the Company, would return something to the shareholders, or there might be a reconstruction under the liquidation of the Bombay Company alone; and in either case there would eventually be a small return to the shareholders. I think myself that, under the circumstances in which we find ourselves, we have no choice—at least, that is my opinion—but, in the interests of the shareholders, to go into voluntary liquidation; for if we do not adopt that course and take what steps a liquidator can take, and a liquidator alone can take, to secure our property by which some small return may be made to the shareholders, but continue to go on as we are now doing, spending what remains by sales of the extra assets of the Company, we might ultimately find there were amounts due which we could not meet, in which case I think we should lay ourselves open to the charge of having conducted the business in a way that would not be honourable to us as directors, and therefore I, for one, would never be a party to such a proceeding. If the shareholders do not feel inclined to go into voluntary liquidation, I can only say that I must tender my resignation at once, as I believe most of my colleagues would, because it would not be an honourable thing for us to carry on the business with the possibility of some creditors getting paid in full by seizure, and others not finding that resource available to them. Therefore, I mean to move a resolution which it will be for the meeting to pass or not:—"That it has been proved to the satisfaction of this meeting that the Company cannot by reason of its liabilities continue its business, and that it is advisable to wind up the same, and that the Company be accordingly wound up voluntarily." I may say that supposing we do not go into voluntary liquidation, in my opinion we should very soon find ourselves in compulsory liquidation, and compulsory liquidation means this, that any small return that might possibly be made to the shareholders under voluntary liquidation would certainly be swallowed up, and there would not be a single farthing that could ever reach the pockets of the shareholders. I beg, therefore, to move that resolution.

Major STRUTT: I beg to second it.

Mr. BULL said that he had lately returned from Bombay, where he had gone carefully into the Company's affairs, and where he thought there were the possibilities of a good business. But it seemed to him that the Company was so entangled with liabilities in England that there was no hope for the shareholders but to follow the course proposed by the chairman. He thought, however, that a pledge should be given by the directors that the work at Bombay should not be imperilled meantime, because that was one of the chief things the shareholders had to look forward to for a return of some part of their money.

The CHAIRMAN believed it would assist the discussion if he mentioned that, supposing the resolution he had proposed were passed, he intended to move another motion appointing a committee of shareholders to advise with the liquidator as to the best way of disposing of the Bombay business, which Mr. Bull thought would eventually yield good results. In fact the Bombay business was now paying its way, small as it was, and if it were enlarged he had no doubt it would pay very well. Still, he thought that under the liquidation they would have a better chance of making a profitable sale of that part of the business than by any other way he knew.

In reply to Mr. Wylds the CHAIRMAN further remarked that with the exception of a very small sum, which would be recovered by the liquidator, all the calls had been paid.

The motion was then put to the meeting, and declared carried.

The CHAIRMAN then said: I will try and explain the next resolution, which is "That Mr. H. Cleland Heywood be and is hereby appointed liquidator of the Company for the purpose of winding up its affairs and distributing the property, and that his remuneration be £45 per month for a period not exceeding six months, and that when engaged on the business of the Company all his travelling and living expenses be also paid." The business of the liquidator, among other things, will be to have the whole of the accounts properly laid out, and I confess I know nobody else but Mr. Heywood who could undertake that duty except at a very great cost to the shareholders, because there is a very considerable body of figures and assets to be dealt with. Mr. Heywood would probably have to go to Bombay to settle the question of dealing with the surplus assets there that are not required on passing over the business in whatever way it is decided eventually to be passed over. It is understood that he will try and keep the lighting business in Bombay as it now exists as a going concern, so as to be able to sell it in the most profitable manner, or do whatever is considered to be the best way of dealing with that which is no doubt a valuable asset. We think that Mr. Heywood, having a full knowledge of the accounts, would be the best man to deal with that branch of the business, as well as, under the advice that he will receive from the committee, to deal with the assets of the Company in other parts of the world. We shall receive some small return from the assets that exist in Egypt There will be also something to be returned from Malta, and also from Madras. He would also have to deal with what there is in Calcutta, leaving the Bombay business as far as possible intact, with the view of seeing whether Mr. Bull or others can see their way to carrying it on or be prepared either to give the present shareholders a certain sum of money for it, or to give them, in a reformed company, some shares, deferred or otherwise. He concluded by formally moving the resolution.

Mr. LATIMER CLARK seconded the motion.

Mr. PATON thought that it would be judicious to have a second liquidator appointed, and suggested Mr. Bull as a most suitable person for that office.

The CHAIRMAN pointed out that there would then arise the grave practical difficulty of a possible disagreement between the liquidators, which would render the liquidation invalid.

The SOLICITOR (Mr. Burt) concurred in this view, and pointed out that the only solution to the problem would be to appoint three liquidators, two of whom would form a quorum.

A brief discussion arose on this point, and it was finally agreed that Mr. W. Bull and Mr. Latimer Clark should be appointed liquidators, in addition to Mr. Cleland Heywood, the two former to receive no honorarium beyond such sums as might be incurred for travelling in the interests of the Company's affairs.

The resolution as thus amended was carried, with one dissentient.

On the motion of Mr. PATON, seconded by a SHAREHOLDER, a hearty vote of thanks was accorded to Mr. Noel for presiding.

The CHAIRMAN in returning thanks, alluded to the keen disappointment which, not only as a shareholder but as a director of the Company, he had experienced at the loss which it had sustained. He was very confident for a year and a half that they had a really good property, so much

Digitized by Google

so that he said to a friend of his that he believed while all the other companies were looking bad this one was likely to turn out a paying concern. It was only quite late in the day, unfortunately, that they found out that they had made the same mistake as other companies had committed—namely, that they had sent out material to India much in excess of what was really required, and as every one knows those things that were sent out and were not used for electrical purposes represented so much money thrown away.

Mr. LATIMER CLARK, in reply to a shareholder, said that if the Government of India had not given an order for all wires to be placed under ground the Company would by this time have been a most profitable undertaking. Its ruin practically dated from the time that order was given.

The proceedings then terminated.

## THE TELEPHONE COMPANY OF IRELAND.

On Wednesday, the 16th inst., the third half-yearly meeting of the proprietors of this Company was held at the offices, Commercial-buildings, Dublin, Mr. E. D. Gray, M.P., in the chair.

The SECRETARY (Mr. James Butterworth) read the notice convening the meeting. The report and statement of accounts were taken as read.

The CHAIRMAN (in moving the adoption of the report and statement of accounts) said he would be excused for not making a very lengthened or elaborate statement, as he had only just left a sick bed, thinking it was his duty to be there. The accounts spoke for themselves, and they recorded a continued and increasing prosperity, and he did not think they required very much elaboration from him. The number of their Exchange subscribers had extended from 411 to 507. That was nearly an increase of 100 to 31st of December last, and that rate of increase, or a very considerable increase, he might say, had been maintained up to the present time. The number of the renters of private lines had increased from 127 to 141, and that showed that the business of the Company was regularly and steadily prospering half year by half year, and, he might say, week by week. They had had considerable difficulties to contend with—with reference to the development of their business—with the Post Office, who claimed to have an absolute control over it. They had, however, succeeded, after lengthened negotiations, in obtaining an extension of the area conferred by their present license from four to five miles radius, which was a very large increase. They had also obtained what was called an ultra-radial extension towards Kingstown; and they had been permitted to extend towards Kingstown so as to include Stillorgan, Monkstown, and Kingstown, and they were now engaged in making preparation for laying the line to Kingstown, which they hoped to have completed as early as possible. This would give greatly increased facilities to the public, and be of advantage to the business of the Company. A considerable number of the six per cent. shareholders had since the last day of meeting agreed to exchange their shares, as was proposed then, for five per cent. preference shares, and there now remained outstanding only 3,720 of the old six per cent. shares, which, it was to be hoped, would shortly be exchanged for five per cent. shares. He had only to say a word as to the attitude of the Post Office, not only towards this Company, but towards telephone companies generally. The Post Office would not grant new licences unless on the condition of the Company agreeing to sell to them instruments which they did not own, and over which they had no control further than the right to obtain the use of them from the parent company. He was told that in England they sought to compel the companies to charge a minimum rate to their subscribers, imagining perhaps that they were doing it in the interest of the public; but it was directly against the interests of the public, because it was throwing impediments in the way of the public obtaining the advantages they would otherwise enjoy. He would give them another instance of the way the department acted towards them. Many months ago he, on the part of directors, wrote to the Postmaster-General, suggesting that they should be allowed to establish in Dublin talking stations, where any person, whether a subscriber to the Company or not, could come and for a small sum speak to any subscriber. The Postmaster-General wrote to him to say that the matter would have his careful consideration, and that he would send a reply. They found their business getting so large that the directors were of opinion that the time had come when they should appoint a managing director. Mr. Arthur Dudgeon had up to the present time acted, but without any special remuneration, and now that they were in a position not only to pay their preference shareholders in full, but also a small dividend on the ordinary shares, they thought it would be only right to give Mr. Dudgeon a sum which, if not adequate payment, would be some remuneration for his services. It was also proposed to vote a sum of £200 to the directors for their services during the last eleven months. If the Board thought it desirable to endeavour to induce other telephone companies in England to take some public action to compel the Post Office department to show its hand in its favour, and take up some comprehensible and reasonable position with reference to telephone development, he trusted they would have the support of the shareholders. He would conclude by moving the adoption of the report and statement of accounts.

Mr. WINSTANLEY seconded the motion, which was adopted.

Resolutions were then proposed, seconded, and duly passed, declaring a dividend of 6 per cent. on the unconverted 6 per cent. preference shares, payable on the 19th April, a dividend of 5 per cent. on the 6 per cent. preference shares converted into 5 per cent. preference shares, and a dividend of 1½ per cent. on the ordinary shares. Mr. E. Dwyer Gray, M.P., Mr. Hermann, and Mr. G. Erichsen were re-elected directors, and a sum of £200 was voted them for their services. Messrs. Kevans and Kean were then re-elected auditors, and a vote of thanks to the chairman brought the meeting to a close.

# COMPANIES' SHARE LIST.

UNIVERSITY COLLEGE, BRISTOL.

DEPARTMENT OF EXPERIMENTAL PHYSICS.

PROFESSOR - - S. P. THOMPSON, D.Sc., B.A.

The THIRD TERM begins on MONDAY, the 28th APRIL.

The Courses of Lectures and Classes in Experimental Physics will be continued.
THE PHYSICAL AND ELECTRICAL LABORATORY IS OPEN DAILY.

IN THE MATTER of Letters Patent granted to JAMES ALFRED KENDALL, of Middlesbrough, in the County of York, for an Invention of "AN IMPROVED METHOD OF GENERATING ELECTRICITY," dated 21st March, 1883, No. 1481.

NOTICE IS HEREBY GIVEN, that the said JAMES ALFRED KENDALL has, under Sections 18 to 21 of the Patents, &c., Act, 1883, and Rules 48 to 56 of the Rules made thereunder, applied for leave to AMEND the SPECIFICATION filed in pursuance of the said Letters Patent by re-arranging the matter of the Specification and the addition of drawings and a description thereof.

Any person intending to oppose such application must leave particulars in writing of their objections to such proposed amendment at the Patent Office, 25, Southampton-buildings, Chancery-lane, London, within one month from this date.

Dated this 10th day of April, 1884.

H. READER LACK,
Comptroller-General.

Agents—Vaughan and Son,
57, Chancery-lane, E.C.

A YOUNG MAN (21) WANTS SITUATION. Moderate knowledge of electricity (theoretical and practical).—Address, X. M., 143, Edgware-road, W.C.

MR. JAMES WHITE, 209, Sauchiehall-street, and 16 and 18, Cambridge-street, GLASGOW, is now prepared to SUPPLY ARC LAMPS (Gray's patent) for general lighting, or for lecture illustration purposes.

Steady and silent in action, and adapted for either battery or dynamo.

Price, with Lantern and Globe complete for ordinary lighting, £13.

Special quotations for Search Lights, or for Arc Lamps fitted in projection lanterns.

Mr. WHITE is also prepared to Quote Prices for GRAY'S SENSITIVE ASTATIC GALVANOMETER (see "Nature," March 6th, 1884).

NOW READY, PRICE 3s.,

THE NEW ENGLISH PATENT LAW,

and the

Patent Laws of all Foreign Countries & British Colonies,

In the form of Analytical Summaries explanatory of the proceedings necessary to obtain and maintain Patents for Inventions at home and abroad.

A. M. & Wm. CLARK, Patent Agents, 53, Chancery Lane, London.

Digitized by Google

## NOTES.

CABLE INTERRUPTED.—The cable between Fortaleza and Maranham is interrupted.

CABLE REPAIRED.—The cable between Rio Grande do Sul and Monte Video is repaired.

THE DRAWBAUGH TELEPHONE.—It is not expected that the Bell *v.* Drawbaugh case will be tried for some months to come.

ELECTRIC LIGHTING AT NEW BRIGHTON.—The Brush Midland Company have lately installed a No. 5 Brush machine at the New Brighton Winter Gardens.

DYNAMOS FOR TELEGRAPHY.—The Philadelphia Local Telegraph Company are using Edison dynamos for their circuits, and they are said to answer very well.

THE TELEPHONE IN GERMANY.—The Chambers of Commerce at Frankfort and Mannheim are connected by a telephone line. The distance between the towns is 80 kilometres.

ELECTRIC LIGHTING AT NOTTINGHAM.—The Brush Midland Company are engaged in lighting part of the premises of the *Nottingham Guardian* by means of 40 incandescent lamps.

APPOINTMENT.—Mr. Nigel M. Arnot, late of the Metropolitan Brush Electric Light Company, has been appointed Electrician in London to the Australasian Electric Light, Power, and Storage Company.

GREAT NORTHERN TELEGRAPH COMPANY.—It is notified that the excess dividend on Great Northern Telegraph shares for the year 1883 will be paid, at the rate of 6s. per share, by Messrs. C. I. Hambro and Son.

TECHNICAL EDUCATION.—The report of the Royal Commissioners on technical education was to be placed in the hands of the printers on Wednesday last, and is expected to be circulated within the next three weeks.

EDUCATION, SCIENCE, AND ART.—The Select Committee on the Administration of Education, Science, and Art, appointed last session, has recommenced its sittings. Earl Spencer has been invited to give evidence.

THE SENEGAL CABLE.—It is stated that the Spanish National Submarine Telegraph Company have asked for a concession from the Portuguese Government to enable them to prolong their communication with Senegal as far as the Congo territory.

ELECTRIC LIGHTING IN NEW YORK.—The Edison lighting station in New York is now connected with over 500 houses, which are wired for nearly 13,000 lamps. Of these 11,272 are actually attached to the conductors and ready for use as required.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The directors of this company, after deciding to place £15,000 to reserve, have resolved to recommend a dividend of 6s. per share on account of arrears of dividend on the First Preference shares.

BOOKS RECEIVED.—"Der Druck-Telegraph Hughes," von J. Sack, Kaiserl Telegraphen-Inspector. Published by Hartleben, of Vienna, Pesth, and Leipsic.—"The Scientific Papers of James Prescott Joule, D.C.L., F.R.S., &c.," published by the Physical Society of London.

DEATH OF HERR MIESSNER.—The *Journal Télégraphique* announces the death of Herr Miessner, who but recently assumed the chief direction of the German Telegraph Service on the death of Herr Budde. Herr Miessner had been in the German Postal Service for some ten years.

TO OUR READERS.—Owing to the impossibility of dealing with the recent papers read before the Society of Telegraph Engineers in the small space left at our disposal in the two last numbers of this volume, we have decided to leave them over for the early numbers of the new volume.

ELECTRIC LIGHTING IN THE COURTS OF JUSTICE.—Owing to the thick fog on Tuesday, the electric lights in the Royal Courts of Justice had to be turned on. They appear to have had a somewhat severe fit of winking, however, in some of the rooms, and particularly in Mr. Justice Stephen's court.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this company for the week ending 18th April, 1884, were £2,409, and for the week ending 25th April £2,527, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

CARBON.—Dr. Aron has discovered that it is possible to render vegetable carbon a good conductor and incombustible by heating it strongly in a vacuum or neutral atmosphere. He brought the results of his experiments in this direction before a recent meeting of the Electro-technical Society of Berlin.

THE SOUDAN.—On Wednesday the wire between Wadi Halfi and Dongola was cut, as also was that between Berber and Mirawi. Up to the time of our going to press nothing had come through to Cairo from the Governor of Berber since Wednesday morning. It is assumed that the telegraph clerks had left the town.

ELECTRIC LIGHTING IN GERMANY.—The *Standard's* Berlin correspondent says that the wharves at Wilhemshaven, Kiel, and Dantzig are to be greatly enlarged in the next three years and provided with the electric light. Seventy torpedo boats and submarine mines are also to be constructed. Stralsund has been fixed upon as the station for torpedo boats.

CENTRAL NEWS *v.* EASTERN TELEGRAPH COMPANY.—This case which we have referred to from time to time during the past three months has occupied the attention of the Lord Chief Justice and a special jury during this week. As the case was not finished when we went to press we prefer to postpone any detailed reference to it for the present. It is probable that it will be finished to-day (Saturday).

SOCIETY OF TELEGRAPH ENGINEERS.—The next meeting of the society will take place on the 8th May, at 25, Great George-street, at 8 p.m., when the following paper will be read :—"On a Method of Eliminating the Effects of Polarisation and Earth Currents from Fault Tests," by Henry C. Mance, C.I.E., member, with some supplementary remarks and illustrative experiments by Latimer Clark, Past President.

EASTERN EXTENSION TELEGRAPH COMPANY.—The Eastern Extension Telegraph Company announce the numbers of 909 Five per Cent. Australian Government Subsidy Debentures of £100 each, which have been drawn for payment at par on July 1 next, at Messrs. Barclay, Bevan, and Co.'s bank. The coupon on the company's Five per Cent. Manila Debentures, due on the 1st inst., will be paid on and after that date at the Consolidated Bank.

SUBMARINE CABLES TRUST.—The revenue of the Submarine Cables Trust, according to the report, amounted for the year ending 15th inst. to £26,176, including £2,185 brought forward. The expenses of the trust reached £1,323, and the two half-yearly coupons, at the rate of 6 per cent. per annum,

Digitized by Google

absorbed £20,340, leaving £3,943 to be carried forward. The thirteenth ordinary meeting of the trust will be held at the offices, 66, Old Broad-street, E.C., on the 13th inst., at 1 p.m.

A Balloon Struck by Lightning.—A heavy thunderstorm broke over Turin on Sunday afternoon, during which the great captive balloon that was to have formed one of the attractions of the week was struck by lightning and destroyed. The ropes broke, and the balloon ascended for about 200 yards, and burst with a loud report. It then caught fire. The balloon contained 1,500 cubic yards of gas. Great consternation prevailed among the spectators, but no casualties are reported.

The Electrical Conference.—The International Conference for the determination of electrical units assembled on the 27th inst. at the Ministry for Foreign Affairs. The proceedings were opened by M. Jules Ferry in a speech, to which M. Broch, the Norwegian delegate, responded. The Conference then confirmed M. Cochery, who, as Minister of Posts and Telegraphs, had taken the chair, in the presidency. Sixty-four delegates, representing twenty-six States, have gone to Paris to attend the Conference.

Accidents from Lightning.—There was but one accident from lightning recorded in France in January, 1883, and in this case the lightning struck the umbrella of a man walking at Dienné. The current was divided by the metal ribs of the umbrella. In February no accidents were recorded at all; but in March, April, and May, the record begins to swell until in June it assumes large proportions. These observations are being regularly kept at different stations in France, and should prove of considerable scientific value.

New Blowpipe.—Mr. Thomas Fletcher, of Warrington, has just brought out a new form of blowpipe specially designed for the utilisation of gas in places where it is more or less a waste product. No. 1 size requires a smith's bellows and a 1½in. gas main. It will burn up to 300 cubic feet per hour, and Mr. Fletcher states that with it he can heat a 3-inch wrought-iron pipe to brazing heat in five to six minutes. He also claims for it the great advantage of not getting hot, so that it can readily be held in the hand.

Trotting Out an Old Idea.—A correspondent writes as follows:—In the issue of April 12, page 123, I find "Kinks in Submarine Cables, &c." It is really amusing to note that the expedient adopted by Messrs. Trott and Hamilton is to make each alternate layer of sheathing cross each other. This method of placing the hempen bedding around a cable previous to its being armoured with wires was adopted by Mr. W. W. Marks, Superintendent of the Bishop Gutta Percha Works of New York city, in the year 1864.—*Electrical World.*

An Electric Bell Case.—At the Luton County Court, a few days since, Mr. F. T. Garrett, manufacturing electrician of Dunstable, sued a man named Delger, of Luton, for £16 16s., for fitting up the defendant's house with electric bells and burglar alarms. To meet this claim the defendant paid £10 into court, asserting that that sum more than covered the value of the work. For Mr. Garrett there appeared his brother, Mr. W. J. Pearson, an architect of Luton, and a local builder, all of whom testified to the excellency of the work done by the plaintiff for defendant. In the end the judge gave judgment for the plaintiff for the amount claimed and costs, without calling on the plaintiff's solicitor to reply to the allegations of defendant's counsel.

City and Guilds of London Institute.—On Monday last, at the meeting of the executive committee, the following gentlemen were elected to professional chairs:—*Chemistry:* Henry Armstrong, F.R.S. *Engineering:* W. C. Unwin, B.Sc. *Mechanics and Mathematics:* O. Henrici, F.R.S. *Physics:* O. J. Lodge, D.Sc. We have but few words to say of this selection, and those altogether of congratulation. The men selected are all strong men—men who can and will make the new institute the centre of scientific activity. We are glad to be able to welcome Professors Unwin and Lodge back to London. The loss to Cooper's Hill and to Liverpool will be great, but these men are among the younger scientific giants, and should naturally gravitate to the scientific centres.

"The Monthly Correspondent."—We have received No. 6 of the *Monthly Correspondent*, which, as our readers have before been told, hails from Madeira, and is kept alive by the staff of the Brazilian Submarine Telegraph Company. The present number is a good one, and contains amongst other things an interesting account of the laying of the duplicate Madeira-St. Vincent cable and the repair of the broken St. Vincent-Pernambuco cable by the cable ship "Scotia." The latter was broken close to St. Vincent, in 115 fathoms of water, and showed unmistakable signs of having been chafed by rocks. The cable was out of work owing to this break for twenty-eight days. The same number also has a good account of a visit paid by three of the company's staff to the West Coast of Africa.

Telegraphic Determinations of Differences of Longitude.—M. de Bernardières conceived the idea, on the occasion of the completion of the cable connecting Callao and Lima with Panama, of uniting the coast of the Pacific with Europe by way of Panama, the Grand Antilles and North America, and also by way of Buenos-Aires, Brazil, and Cape de Verde. The result of his experiments, made in conjunction with the captain of the "Fleuriais," a French ship, and recently communicated to the French Academy of Sciences, was that the difference between the values obtained for the longitude of Valparaiso by way of Buenos-Aires only differed from those obtained by way of Panama by ·28sec. The final results obtained were for Valparaiso:—Longitude, 4h. 55min. 53sec., 97°; latitude, 33°, 2h. 10min. 1sec. For Buenos-Aires:—Longitude, 4h. 2min. 49sec, 88°; latitude, 34°, 36h. 29min. 8sec.

The Turin Exhibition.—A correspondent at Turin writes that the electrical section of the International Exhibition is not likely to be in order for a week or two, although the exhibition itself has been opened. Taken as a whole, our correspondent says that the exhibition is a real success, and shows the industrial progress made by Italy since the Milan Exhibition in 1881. "As far as I can see at present," he says, "the International Exhibition of Electricity will not be a very extensive one, but there will be many things of interest. The motive power for dynamos will consist of two steam engines, of 200 horse-power each, and together with the portable, semi-portable engines and gas motors, the total power at disposal will be about 600 horse-power. Amongst the attractions there will be a plant of Gaulard-Gibbs' system, the only one competing for the premium of the Government of 10,000 francs, and of the town of Turin for 5,000 francs, for the best means of transmitting electric energy to great distances."

Electric Lighting Station in Philadelphia.—The Brush electric light station at Philadelphia is a building of one high story, 90ft. by 106ft. The power is derived from a pair of Corliss engines, capable of developing 500 horse-power, and eight Porter-Allen 50 horse-power engines. These serve nineteen dynamo machines, which will have a capacity, when

Digitized by Google

the new armatures are put in, of about 1,000 lights. At present, says an American contemporary, they supply a current to 725 lamps, of which 200 are day lights. The Porter-Allen engines are coupled direct, but the Corliss distribute their power by means of two lines of shafting. There are twenty-five exterior circuits. The switchboard is admirably arranged for making connection from any machine, and each machine has a current switch and a tablet for showing what are the connections of each machine for the day. The plant is worked with a great deal of care and system. Tests for ground are made over the lines day by day; every fire alarm is followed up by a man from the station in case electric light wires have to be cut, and there are attached to the station repairing, testing, and supply branches. The dynamo room is 66ft. by 64ft., and the boiler room 38ft. by 66ft., and it is proposed now to put another story on the building for more dynamos to run Swan lamps, with storage batteries.

SUBMARINE ELECTRIC LAMP.—Last Monday evening some very interesting experiments in submarine electric lighting were conducted on the Clyde, at Greenock. The "Tilly," a vessel built by Messrs. Hanna, Donald, and Wilson for the fisheries at Batavia, has been fitted with machinery to supply current for a 15,000 candle-power lamp, which it is intended to lower into the sea for a depth of ten fathoms or less, as the exigencies of the drift net fishing require. The whole of the electrical apparatus, as well as the gearing for raising and lowering the lamp, have been supplied by Messrs. Paterson and Cooper, the current being supplied by one of their No. 4 dynamo machines, coupled direct to a Gwynne high speed vertical engine, and running at 650 revolutions per minute. The lamp, which is enclosed in a flint glass cylinder 9½in. diameter, is suspended from a davit over the vessel's side, and the two conductors consist of finely stranded copper cord enclosed in india-rubber hose. These conductors pass over pulleys on the end of the davit, and the lamp is raised or lowered by a winch fitted to the bottom of the davit. The trial lasted for four hours, during which time the lamp was submerged, and kept alight with the full current of 60 amperes through it. The appearance on the surface of the water caused by the submerged lamp was very remarkable and pretty. The whole installation was supplied on the suggestion of Mr. John Hayes, C.E., of Leadenhall-street, E.C., and partly as the result of his experiments in this direction. The trial, which gave perfect satisfaction to all concerned, was conducted by Mr. W. B. Esson, Messrs. Paterson and Cooper's electrician.

LIGHTNING PROTECTORS IN SWITZERLAND.—In an article in the last number of the *Journal Télégraphique* on "Lightning and its Effects on the Telegraph Lines in Switzerland," M. Rothen remarks: "In Switzerland the instrument which is most sensitive to atmospheric discharges is the lightning protector of the telegraph offices. There are two systems in use—one, the points protector, is composed of a copper-plate connected with the line and a plate connected to earth, the two plates being separated by an interval of about 1 centimetre. There are two screws in the upper plate pointing downwards, and two in the bottom one pointing upwards, the points of which are but $\frac{1}{10}$th of a millimetre distant from either plate. The second and more general system in use also consists of a plate connected with the line and another with earth, but the former rests on the latter, and is merely separated from it by a paper strip ·06mm. to ·1mm. in thickness. Weak discharges leave marks on these paper strips in the form of pinholes with brown edges. It is very easy to produce the same effects with an electrical machine. This system of lightning protectors is therefore quite sufficient to indicate entirely harmless discharges. As the discharge increases so does the size of the holes, which become star-shaped; the paper is burnt, honeycombed, pressed on one side, and metal contact is established between the plates. With still stronger discharges the metal is attacked, hemispherical depressions are produced in it, and sometimes the shock is strong enough to smash the glass covering of the protector into a thousand pieces. Finally we come to a point when the protector is powerless to completely protect the apparatus, and when the receiver, relay, galvanometer, and key suffer more or less damage. There is, again, a third system in use in Switzerland which is still more delicate, and that is a protector with seven plates, but this is only used at Basel and in the tunnels of the St. Gothard line. With this protector we can determine numbers of small discharges which occur without detonation and without spark, and indeed with a clear sky."

ELECTRIC LIGHTING IN DONCASTER.—A correspondent writes:—"Messrs. Robinson and Hanley have adopted the electric light in their new roller mill at Doncaster. The installation consists of one Crompton-Bürgin dynamo of the self-regulating type and fifty Swan incandescent lamps of 20 candle-power each, which light the entire premises, including offices, stables, and yards. The dynamo is placed in the engine house, and is driven from a countershaft at about 1,600 revolutions per minute. Cut outs or safety fuses are provided at the junctions to the lamps, and also at the main switchboard, which render it impossible to have any fire. We had the pleasure of seeing it at work on Wednesday night, and we were highly delighted with it. The price of gas in Doncaster is 2s. 10d., and taking all things into consideration the electric light will leave a considerable balance in its favour at the year's end. Assuming the lights run 2,000 hours, the working cost would be:—

| | | | |
|---|---|---|---|
| Renewals of lamps ..... | £12 | 10 | 0 |
| Oil and stores, say ..... | 5 | 0 | 0 |
| Attendance, 5s. a week ..... | 13 | 0 | 0 |
| | £30 | 10 | 0 |

whereas for same quantity of light by gas we should require 83 gas burners, using 5 cubic feet each per hour, that is, $83 \times 5 \times 2{,}000 = 830{,}000$, which at 2s. 10d. = £117 11s. I have not reckoned the cost of fuel, but this would not exceed 3lb. of coal per horse-power per hour. That is, $\frac{6\frac{1}{2}\text{ H.P.} \times 3 \times 2{,}000}{2{,}240}$ $= 17\frac{1}{2}$ tons; $17\frac{1}{2}$ tons at 10s. = £8 15s. I have not added interest on the plant, because I consider the many advantages it has over gas will more than compensate for the outlay. The contract has been carried out by Mr. Wilson Hartnell, electric light contractor of Leeds, who during the past season lighted most successfully many mills and ironworks in this district."

THE GILLETT TELEPHONE.—In the course of a detailed and well-illustrated description of the Gillett long-distance telephone the *Electrical World* says:—"Mr. Gillett has devised a new and original form of contact, and in order to improve the results still further he has multiplied these contacts and grouped them in a peculiar way so that they may strengthen but especially 'correct' each other. Each contact consists of a metallic needle attached to the diaphragm of the transmitter and moving with it, its free end passing through an opening into a small recess where it penetrates slightly into a mass of carbon grains, or particles that are more or less compactly held together *under compression* between elastic cushions. In a contact of this construction there are doubtless several actions that conspire to accomplish the object desired—large variations of resistance. In addition to the variations of contact pressure produced at

Digitized by Google

the point of the needle it is not improbable that a certain amount of pressure is transmitted to the carbon particles, and also that a certain degree of molecular vibration must result in these particles themselves. It is quite certain that the microphonic action is not produced merely at the end of the needle, but that it involves the aggregation of carbon particles as well, for Mr. Gillett has found a special advantage in using these particles instead of fine powder. His experiments have led him to give a preference to rough-hewn granules that are covered with excrescences like crushed ore, and he prepares them especially for this purpose from retort carbon. He subjects the carbon to a kind of stamping or crushing process in a mortar, after which the 'grist' is sifted through a fine sieve having 60 meshes to the inch. By this operation the particles are freed from carbon dust and powder. They are now sifted through a 30-mesh sieve, and the particles which are small enough to go through are those used in the transmitter contacts. When examined with the microscope these particles seem like so many craggy boulders full of rough and sharp edges. These projections when delicately compressed against each other must necessarily form sensitive microphone contacts."

Overhead Wires in Wandsworth.—On Tuesday the case of the Wandsworth Board of Works *v.* the Postmaster-General came before the Railway Commission, consisting of Sir F. Peel, Mr. Price and Mr. Millar, Q.C. It was an application by the Board to restrain the Post Office Department from erecting certain overhead wires in the Wandsworth district. The case itself was heard before Mr. Paget, in the Wandsworth Police Court, who, under certain conditions, gave the Postmaster-General power to place some overhead wires across and along streets and public roads in the district, as against the contention of the District Board of Works that the wires should be laid underground. The Wandsworth district, as conjoined under the Local Board of Works, combines many localities, from Lambeth on the east to Putney on the west, and includes Tooting, Balham, Wimbledon, Battersea and Putney. Some of the wires which the Post Office desired to place were for police and fire alarms, and Mr. Paget's award was in favour of one of the proposed lines being underground, this being from the Clapham Branch post-office to Clarence-road; the others, 16 in number, were allowed by Mr. Paget to be overhead wires. The District Board now appealed, under the Telegraphs Acts, 1863 and 1878, to the commissioners from the decision of Mr. Paget, and in the hearing there were 15 cases of wires to be decided, one being withdrawn. The commissioners had before them a very large map of the widely extending locality, in order that they may decide whether the refusal of the Wandsworth District Board to assent to Mr. Paget's award is "unreasonable and unjustifiable." Mr. Philbrick, Q.C., with whom was Mr. R. O. B. Lane, represented the District Board; while the Solicitor-General, with whom was Mr. Casserley, appeared for the Postmaster-General. The case occupied the whole of the day, and it was claimed for the applicants' side that the overhead wires would be dangerous to the community in suburbs increasing greatly in population. The evils of these overhead wires in stormy and snowy weather was pressed. The evidence given before Mr. Paget was brought to the commissioners' attention, and the commissioners adjourned the case until Thursday.

Electric Lighting in Mills.—M. C. Visseaux, proprietor of the Stenay Mills on the banks of the Meuse, writes as follows to *Cosmos Les Mondes*:—"We have had the electric light fitted up in our works, offices, and private houses by the firm of Sautter and Lemonnier. The installation was completed on the 11th January last, and since that time the light has worked without a single stoppage. The electric generator is a self-regulating Gramme machine, type P-A, giving 50 amperes at 1,500 revolutions per minute, and having an E.M.F. of 53 volts at the brushes. With this machine if the armature speed be kept constant we have a beautifully steady light, whatever may be the number of lamps alight, providing that only 40 are alight at one time, this being the maximum number it will feed. We can put out as many lamps as we like without inconvenience, and without in the least altering the light given by the others, by keeping the speed of the machine constant. To drive this dynamo when 40 lamps are in circuit an average of 300 litres of water per second is required, with a fall of two metres, and a wheel giving a return of 70 per cent., or about 4 horse-power. The main circuit consists of a cable of eight copper wires of $\frac{11}{10}$e mil. each. Branch circuits lead from this, each having four Swan lamps of 20 candle-power in it. These circuits are composed of copper wires $\frac{7}{10}$e mil. Cut-outs are placed at the junction of each branch circuit with the main circuit. These have three times been called into action, owing to shortcircuiting of some of the wires, and have each time prevented any damage to dynamo, lamps, or conductors. We can only congratulate ourselves on this method of lighting, which is certainly astonishingly simple. The installation has not cost much, maintenance is easy, and superintendence a cipher. In a word, it is the most economical means of lighting." An editorial note is appended to this letter, stating that the writer has forwarded a table giving the exact number of hours during which each lamp has been alight during the three months. The results are as follow:—Out of 40 lamps, 22 have been but little in use, and may be neglected; the 18 remaining have burnt during 16,276 hours, or an average of 904 hours per lamp; and among these seven have been working for 1,147 hours each, and are still going.

Detection of Zinc and Lead in Presence of Iron.—In a recent number of the *Comptes Rendus* M. A. Deros gives the following instructions for the detection and estimation of zinc or lead in the presence of iron, viz.:—*Zinc.*—The hydrochloric acid solution of 1 gram of the substance is poured gradually, with agitation, into an excess of ammonia, and when cold the mixture is electrolysed in a platinum capsule which acts as the positive electrode, the negative electrode consisting of a platinum spatula or a coil of platinum wire. The current employed should give 300—400 c.c. of detonating gas per hour. Care must be taken to keep the liquid ammoniacal, and after three or four hours the negative electrode is withdrawn, carefully washed, and then treated with a few drops of dilute sulphuric acid, which dissolves the greyish deposit. The solution is evaporated to dryness in a platinum dish with addition of a few drops of cobalt solution and strongly heated; a green residue shows the presence of zinc. In order to estimate the zinc, the solution of 1 gram of the substance is treated as just described, the negative electrode consisting of a sheet of platinum 3 cm. broad and 4—5 cm. long. After 12 hours the zinc will be completely precipitated, which can be proved by placing a new electrode in the liquid. The negative electrode is rapidly washed by immersing it in water, care being taken not to detach any of the somewhat loosely adhering deposit, and is then immersed in a solution of potash or soda of 8° or 10° B., which dissolves only the zinc. The alkaline solution is again electrolysed, the zinc being deposited as a firmly adherent crust on a weighed platinum cone. The deposit is washed successively with water, alcohol, and ether, and dried at 90—100°. It is advisable to wash with water

Digitized by Google

before interrupting the current. *Lead.*—1 gram of the finely powdered substance is placed in a conical flask with 3 or 4 grams of pure cadmium, and very gently warmed with dilute hydrochloric acid. When the solution is complete, and no bubbles of gas are given off from the cadmium, the lead is completely precipitated. The liquor is carefully decanted off, and the residue washed several times by decantation. Five or 6 c.c. of nitric acid are then added, and the solution of lead and cadmium is transferred to a crucible which acts as the negative electrode, the positive electrode being a weighed platinum cone. Rather less battery power is required than in the case of zinc, and in four or five hours the lead is completely precipitated on the positive electrode in the form of peroxide, which is washed with water, dried, and weighed. This process will detect 0·0005 gram of lead in one gram of substance. —From the *Journal* of the Chemical Society for March.

Sixpenny Telegrams.—In the course of the recent Budget Debate in the House of Commons Dr. Cameron deprecated the postponement of the reduction in the price of telegrams. He took exception to the setting down of the cost of new appliances, which were really a judicious investment under the head of expenditure, in the same way as the money frittered away in moving about the Wellington statue, or in respect of the Egyptian war. The average day's work in each office was only half an hour for one operator, yet it had been thought necessary to make provision for an increased staff of telegraphists. The preparations which had been begun would be left half done.—Mr. Fawcett said he should have been extremely glad if the position of Post Office finance generally would have allowed of the reduction in the cost of telegrams at the date originally fixed. But any one who had listened to the able statement of the Chancellor of the Exchequer must have come to the conclusion that unless he was prepared to say that the right hon. gentleman's estimates of revenue were unusually gloomy there would be no margin available to make up the necessary deficiency. He rather thought that, considering the present industrial condition of the country, the estimates might be considered over-sanguine. The Chancellor of the Exchequer was left with a balance of £270,000, and therefore to have reduced the price of telegrams on the 1st of October this year, as first proposed, would have absolutely left him with no surplus at all. Probably, as a matter of fact, the introduction of the sixpenny telegram would not have involved a loss of more than £60,000 or £70,000, but the principle on which the Post Office had hitherto been administered in this country had been that all improvements should be carried out by income, so that in the Post Office they had no such thing as a capital account. Had the sixpenny telegrams been introduced this year instead of next, the Chancellor of the Exchequer would have been compelled to spend during the current financial year the whole of the amount required from capital expenditure instead of being able to spread it over two years. There would be no such waste in the matter of the preparations as had been supposed, as the work was only suspended. Some 15,000 miles of new wire had to be set up, and now this important undertaking would not have to be pushed forward with such extreme haste as had been anticipated. Moreover, as they had ten months longer to complete the work, they would have a better trained staff, and therefore there would be less chance of the general telegraphic business of the country being dislocated. Notwithstanding that improvements had been made in the position of the staff of the post and telegraph departments involving great expense the profit was now £200,000 more than it was five years ago. He regretted that the parcels post operations had not been so satisfactory as had been expected. The estimate of the number of parcels had not been far wrong, but the weight of the parcels, and therefore the revenue, had been below the estimate. The parcels post had to be organised without the slightest risk of dislocating the letter service, but now the amount of business was being ascertained by experience, reductions in expenditure were every day taking place, and whether the business was great or small he felt sure that the expenditure could be adjusted to the amount of business done, whatever it might be, and that there would soon be a balance between revenue and expenditure. The public had gained an advantage indirectly from this expenditure, because instead of destroying private agency it had stimulated private enterprise.

The London Central Electric Railway.—The opposition by which the Metropolitan Board of Works is endeavouring to prevent the passage of the London Central Electric Railway Bill through committee does not seem to be quite that sort of work for which metropolitan rates are placed at the disposal of that body. The railway is projected with a view of providing that communication between Charing Cross and Regent-street, Oxford-street and the City, the want of which has been so long and seriously felt by the enormous numbers of people passing between south-western and northern London. Along the route of the line the Board of Works has already powers to construct some new streets. Now, the Electric Railway Company can show that the line projected, which will be about two miles in length, can be constructed for about £395,000. It is proposed that the share capital of the company should be £500,000, with borrowing powers to one-third more than this, or a total of about £670,000. During the course of the inquiry on the Bill on Tuesday by the Select Committee of the House of Commons, presided over by Sir Joseph Bailey, a great many questions, which were obviously too absurd to carry any weight, were asked by the opposition respecting the working of the railway by electricity, and Mr. Crompton, Mr. A. Siemens, and others were examined; but it does not seem that any real opposition to the scheme can be maintained on the ground either of electrical or constructive engineering difficulties. The plans are made with a view of working thirty trains each way per day at from ten to twelve or fifteen miles per hour. With the small cost above mentioned, with the great traffic which it is admitted on all hands that there would be, with the moderate cost of working which would be attained with the system, as proved elsewhere, it can easily be seen that fares might be very low. The Board of Works object ostensibly on the ground of interference with easement. This is absurd, because the electric line is proposed to be constructed below the level of all sewers, and therefore below the level of any future railway of the Metropolitan sort which could be constructed above it. Stripped of all varnish, the Board of Works' objection means black mail, and it is said that the Board demands that a sum greater than the whole sum necessary to make and work the railway should be paid by the company to help to construct the streets, and to pay for the property along both sides. The demand is so absurd that it seems almost impossible that it can be true. Not only is the railway to be taxed by the local rates, but it is ready to pay the Board of Works a reasonable sum for right of way, and it cannot be expected to pay to construct whole new streets. London should pay for these new streets in a legitimate way, not allow the Board of Works to levy an enormous permanent tax on intercommunication chiefly to be paid by the working classes. After two days examination, however, the Committee found the preamble not proved.

## ELECTRO-CHEMISTRY.—INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 558.)

**Separation of Manganese.**—Mn. Atomic weight = 55·0. A cation. By the simple immersion of sodium amalgam in an acidulated solution of a salt of manganese, metallic manganese is deposited and alloys with the mercury (Roussin, *Chem. News*, Vol. XIV., p. 27 ; Watts's "Dictionary of Chemistry, Vol. VI., p. 802). According to Phipson, magnesium deposits manganese upon itself by simple immersion in a neutral solution of a manganous salt. (*Proceedings* Royal Society, 1864, Vol. XIII., p. 217 ; *Chem. News*, Vol. IX., p. 219.)

Manganese is not deposited in the metallic state by a separate current from its neutral or acid solutions, but as hydrated manganese peroxide. In very dilute solutions of this metal containing much nitric, or a mixture of nitric and sulphuric acids, permanganic acid is formed, and colours the liquid. (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., p. 284.)

**Formation of Peroxide of Manganese.**—The electrolysis, by a separate current of a solution of nitrate or acetate of manganese, yields a peroxide at the anode (W. Wernicke, Watts's "Dictionary of Chemistry," Vol. VII., p. 899; *Jour. Chem. Soc.*, Vol. IX., p. 307). Solutions of salts of manganese yield peroxide at the anode; one composed of one part of manganous chloride dissolved in eight of water, yields with a platinum wire cathode very beautiful alternate rings of purple green, golden yellow, and blue, surrounded by a broad belt of golden yellow. With a solution composed of one part of acetate of manganese and fifteen of water, one uniform tint is invariably produced, first golden yellow, then purple, then green (B. Böttger, *Pogg. Ann.*, Vol. L., p. 45).

**Electrolysis of Manganous Fluoride.**—$MnF_2$. Molecular weight = 93·0. I melted some fluoride of manganese in a platinum crucible, and employed two spirals of platinum wire as electrodes, and a current from six large Smee's cells. The conduction was moderate, and gas was evolved from the anode. In a few minutes both the cathode and the crucible became quite rotten by the union of the deposited manganese with the platinum. The anode was not corroded. I also melted the same salt in a crucible of copper, and passed the current by means of a sheet platinum anode and sheet copper cathode during half an hour. The conduction was free, abundance of gas was evolved from the anode, but none from the cathode, and it ceased on stopping the current. The deposit on the cathode was black, and did not evolve hydrogen with dilute hydrochloric acid, and was therefore not metallic manganese. The crucible was much corroded at the line of surface of the liquid.

I also electrolysed a dilute solution of fluoride of manganese by a current from six Grove's cells and electrodes of platinum. Much heat was evolved, gas was set free at the anode, and a film of black deposit formed upon the cathode. By similar treatment of a saturated solution of the salt, not containing any free hydrofluoric acid, a film of purple colour was instantly formed upon the anode, but it dissolved quickly, and did not colour the liquid. Gas came from both electrodes freely; the liquid also became heated. No solid deposit was obtained.

**Electrolysis of Manganous Chloride.**—$MnCl_2$. Molecular weight = 126. By the simple immersion of an amalgam of sodium in a saturated aqueous solution of this salt, Giles deposited manganese upon the surface of the amalgam (*Phil. Mag.* 4th Series, Vol. XXIV., p. 328). It produces a viscid amalgam of manganese and mercury. According to S. Kern, magnesium deposits only manganous oxide (*Jour. Chem. Soc.*, 1876, Part 2, p. 479).

Bunsen filled a porous cell with a hot, saturated, aqueous solution of this salt, placed it in a charcoal crucible containing hydrochloric acid to the same level, kept the whole arrangement hot, and passed a current from four Bunsen's cells from the crucible to a platinum wire immersed in the manganous solution. Metallic manganese was easily and freely deposited; but if the density of the current at the cathode was reduced by any means, or the concentration of the solution diminished, black manganous manganic oxide alone was obtained. (*The Chemist*, No. XI., August, 1854, p. 685; Watts's "Dictionary of Chemistry," Vol. II., p. 438.)

**Electrolysis of Manganous Sulphate.**—$MnSO_4$. Magnesium deposited hydrated manganous oxide from a neutral solution of this salt, but from the same solution acidified it deposits metallic manganese (Commaille, *Chem. News*, Vol. XIV., p. 188).

For the electrolytic analysis of compounds of manganese, see *Jour. Chem. Soc.*, 1877, Part 2, p. 924, Vol. XXXVIII., p. 284, Vol. XLII., 1882, pp. 896, 1320; *Chem. News*, Vol. XLVI., p. 105).

**Deposition of Chromium.**—Cr. Atomic weight = 52·5. A cation. A slightly acidified solution of chromic chloride or other chromic salt yields with sodium amalgam an easily decomposable liquid alloy, which, when heated in a stream of hydrogen or vapour of naphtha, loses its mercury and leaves metallic chromium in a spongy state. The liquid turns green previous to reduction (Bunge, Watts's "Dictionary of Chemistry," Vol. VI., p. 816 ; Roussin, *ibid*, Vol. VI., p. 449; Vincent, *Phil. Mag.*, 4th Series, Vol. XXIV., p. 328). Magnesium precipitates only the hydrated sesquioxide of chromium from a solution of chromous and chromic chloride. (Commaille, *Chem. News*, Vol. XIV., p. 188.)

By means of a current from six Grove cells with platinum electrodes, I electrolysed a strong solution of fluoride of chromium containing some free hydrofluoric acid and a little hydrochloric acid. The liquid soon became hot; no gas was liberated at the cathode, but chlorine and ozone were set free at the anode, which was not corroded. I also passed a current from five Smee's elements, by means of electrodes of platinum, through some acid potassic chromate in a state of fusion. A deposit slowly formed upon the cathode.

By operating in a similar manner upon a concentrated solution of chloride of chromium as upon one of manganese, Bunsen deposited chromium readily. The deposit appeared like iron, but was less affected by damp air. It resisted the action of boiling nitric acid, but was soluble in hydrochloric or dilute sulphuric acid. It was friable, and presented a polished surface on the side next the cathode. On diminishing the density of the current a black powder was deposited, containing more oxygen in proportion as the current was decreased. Adding protochloride of chromium had the opposite effect; *i.e.*, it caused metallic chromium to be deposited. (*The Chemist*, No. 11, Aug. 1854, p. 686, Watts's "Dictionary of Chemistry," Vol. 2, p. 438.)

For the electrolytic analysis of compounds of chromium see *Jour. Chem. Soc.*, Vol. XLII., p. 896.

**Deposition of Uranium.**—Ur. Atomic weight = 120. A cation. Magnesium deposits gold coloured hydrated sesquioxide of this metal by simple immersion in an aqueous solution of the oxalate of uranium (Commaille, *Chem. News*, Vol. XIV., p. 188). Magnesium decomposes an aqueous solution of uranic nitrate with evolution of hydrogen, and produces uranic oxide (S. Kern, *Jour. Chem. Soc.*, 1876, Part 2, p. 479). I melted some fluoride of uranium in a platinum crucible, and added to the liquid some crystals of silicon; the salt was not decomposed.

Solutions of uranium in mineral acids are not precipitated by a current from two to four Meidinger Pincus elements, but the nascent hydrogen reduces the uranic to uranous oxide. From neutral solutions it is separated in very small quantities of a yellow colour. Alkaline solutions containing acetic, citric, or tartaric acid or sugar also deposit by electrolysis small quantities of uranium. The deposited uranium does not readily dissolve in dilute acids. (Schicht, *Chem. News*, Vol. XLI., p. 280.)

I passed a current from six Grove's cells, by means of platinum electrodes, through an aqueous solution of fluoride of uranium. Much gas, having the odour of ozone, was evolved at the anode, and the liquid became hot. On adding some aqueous hydrofluoric acid the conduction became very free, and more gas was liberated from both electrodes, but no solid deposit was formed.

I also fused some fluoride of uranium in a copper crucible, and passed a current from six Smee's cells through it by means

Digitized by Google

of a platinum wire anode, using the crucible as a cathode; a little gas was set free at the anode, and the crucible melted. A second trial was made, using a platinum crucible, and two spirals of platinum wire as electrodes, and the current continued during one hour. Conduction was very free, much gas was evolved from the anode, but none from the cathode; a bulky deposit quickly formed upon the negative spiral, especially on the side towards the anode. The deposit weighed 43·66 grains, and consisted of hard jet black crystals. The anode was not corroded. In a third trial four Grove's cells were employed, and a special apparatus devised and employed to collect the evolved gas, and about five cubic inches were obtained. The crystals were not metallic uranium; they were insoluble in boiling water, but soluble in cold dilute hydrofluoric acid, without evolving gas. About one-fourth of the deposit consisted of a fine crystalline powder, nearly of the colour of copper, but darker, and was composed of the crystals, with a film of less reduced fluoride upon them; they evolved gas in cold nitric acid, or in hot dilute nitric acid. They were not fused by heating alone to redness upon platinum foil, but if caustic potash was added they oxidised. I also electrolysed a fused mixture of the pure fluorides of uranium and potassium with platinum electrodes; the results were very similar, except that the deposit upon the cathode fell off as fast as it was formed, and the crystals had to be extracted by dissolving the cooled saline mass in slightly diluted and hot hydrochloric acid. They were very much like those of silicon; their form was that of a short pyramid with a square base. The anode was very slightly corroded and made bright by the action, and twenty cubic inches of gas were collected from it.

By electrolysis with a separate current, uranium is obtained in small quantity only, even from the completely neutral solution of the oxide, as a yellowish grey metallic precipitate, soluble in hydrochloric acid. (C. Luckow, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 284.)

On passing the current from two elements of a bichromate of potassium battery through an aqueous solution of uranium acetate, formiate or nitrate, bright yellow uranium oxide, $Ur_3 O_4$, was separated at the cathode, and gradually became black. No uranium remained in the solution after the current had been passed two hours. The black compound was uranic uranous oxide, containing 81·13 per cent. of uranium (E. F. Smith, *Chem. News*, Vol. XLIII., p. 61, also *Jour. Chem Soc.*, Vol. XXXVIII., p. 284, Vol. XL., 1881, p. 3). According to the same author, molybdenum, tungsten, vanadium, didymium, and cerium are not completely precipitated from their solutions by the voltaic current.

For the electrolytic analysis of compounds of uranium see *Chem. News*, Vol. XLII., p. 331.

**Separation of Tungsten.**—W. Atomic weight = 184. A cation. When tungsten trioxide solutions are reduced by zinc, the final product of the action is tungsten dioxide (O. Freih, *Jour. Chem. Soc.*, 1883, Vol. XLIV., p. 785). I fused some sodic tungstate to a clear liquid in a porcelain vessel, and electrolysed it by means of a current from five Smee's elements, a gas carbon anode, and a platinum wire cathode. The conduction was moderately free, gas was evolved from the anode, and at the cathode black matter was set free, floated, diffused in the liquid, and became partly redissolved. According to E. F. Smith, neutral solutions of the tungstates are not affected by the current. (*Chem. News*, Vol. XLIII., p. 61.)

**Separation of Vanadium.**—Va. Atomic weight = 137. L. Schicht dissolved vanadium chloride in water containing hydrochloric acid, and electrolysed the solution. No deposition took place in the blue liquid, the vanadic acid being merely reduced to oxide (*Chem. News*, Vol. XLI., p. 280, and XLII., p. 331). I electrolysed a solution composed of vanadic acid dissolved in pure dilute hydrofluoric acid, by means of a current from 10 Smee's elements, with a gas carbon anode and platinum cathode. Gas having an odour of ozone was set free at the anode. I also saturated dilute sulphuric acid with pure vanadate of ammonia, and electrolysed the solution with platinum electrodes, and a current from four zinc and platinum elements excited by dilute sulphuric acid. Conduction was very sparing; the solution slowly became of a very intense bluish black colour at the cathode, and a jet black powder of some thickness was deposited upon it.

For the electrolytic analysis of vanadium compounds see *Jour. Chem. Soc.*, Vol. XLII., 1882, p. 896.

(TO BE CONTINUED.)

## THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

The Ancients, who were no doubt sufficiently wise in their own generation, were wrong in concluding that the celestial bodies moved in circles because circular motion was perfect, without first ascertaining that they did move in circles; but their erroneous conclusion did not arise from any imperfection in the circle. For although the researches of the Moderns have established that a body, unacted upon by force, will move in a straight line, thus leading to the opinion that it is the straight line that is perfect, which again is corroborated by the decision of the powerful thinkers who have settled that simplicity is perfection, yet the ancient preference for the circle is defensible, since it is the simplest of all curved lines. Nothing can be rounder than a circle. And that there is a natural tendency for both the human body and understanding to move in circles is proved by the accounts of the doings of belated travellers in the wilds, and by the contents of a great mass of books. But to enter upon this subject would lead us too far afield; suffice it to say that in the following the circular motion of electricity, whether such be considered perfect or not, is involved from beginning to end, and that without it the mathematical difficulties to be surmounted would be far greater.

When a circular current changes its strength, the lines of induced E.M.F. are also circles, in planes parallel to the first, and centred upon the same axis. The lines of E.M.F. arising from variations in the strength of currents in any number of circular conductors in parallel planes, with a common axis, coincide in direction with the circuits themselves. The circular conductors, so far considered to be of infinitesimal sections, need not be all insulated from one another; so we see at once that the lines of flow of the currents induced in any conductor shaped as a solid of revolution whose axis is that of the inducing currents are also similar circles, and therefore the lines of E.M.F. arising from the variation of these induced currents form similar circles, so that the circular characteristic is not lost. A circular cylinder, or straight hollow tube, forms a special and simple example. A further and remarkable simplification occurs when the circular conductors are packed closely and regularly together to form themselves a long hollow tube, within which the solid or hollow core is placed, their axes coinciding. The magnetic force due to equal current per unit length of the solenoid is nearly uniform in strength throughout the space within, and is parallel to the axis. If infinitely long the force would be quite uniform, and there would be no force outside the coil. Then the induction currents in the core would be the same all along, and any thin slice cut out perpendicular to the axis would serve to illustrate the state of the whole core. With a practicable coil of finite length, the spreading out of the lines of force when nearing the ends of the coil naturally weaken the induction currents in the core there, but for obvious reasons we treat our coil and core in the following as forming a portion of an infinitely long similar coil and core, thus making the magnetic force due to the coil and core currents a function of the distance from the axis only, and not of distance along the axis also.

*Geometrical and Electrical Data.*

Let $l$ be the length of the coil, $a$ its inner, and $a+b$ its outer radius, and $c$ the radius of the core, which may be equal to or less than $a$. Also let, in the first place, the core be solid. Divide the core into an indefinitely great number of thin hollow tubes. Since, for reasons mentioned above, there is no motion of electricity from one tube to another, these tubes may be considered to be insulated from one another, so that the electrical system is reduced to an infinite number of known linear circuits. We know the paths of the currents,

Digitized by Google

we have to find their strengths, and that of the magnetic force and other quantities concerned.

Let $r$ be the radius of one of these tubes, $h$ its small thickness, $l$ its length, $\rho$ its specific resistance, and $R_1$ the resistance of the tube, *i.e.* to the flow of electricity round it in the manner considered. The value of $R_1$ is obviously

$$R_1 = 2\pi r\rho/hl \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Let the unit current flow round the tube, giving a current $1/l$ per unit length. The magnetic force it produces is of strength $4\pi/l$ within, parallel to the axis, and zero without. The section being $\pi r^2$, the surface integral of the magnetic force is therefore $4\pi^2 r^2/l$, and of the magnetic induction $\mu$ times as much, $\mu$ being the permeability of the matter within the tube. Hence the coefficient of self induction of the tube is

$$s = (2\pi r)^2 r/l \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

The quotient of this by the resistance is the time constant of the circuit, say $a$, where

$$a = 2\pi r h\mu/\rho \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

and is the time a current left in the tube without other E.M.F. than that arising from its own self-induction would take to fall in strength from $e$ to 1 or 2·71 : 1 ; the E.M.F. of induction round the tube being equal to the rate of decrease of the amount of induction through it, which gives at once, by Ohm's law, if $\gamma$ be the current at any moment,

$$-s\dot{\gamma} = R_1\gamma, \qquad \text{or} \qquad \gamma + a\dot{\gamma} = 0,$$

whose solution is $\gamma = \Gamma e^{-t/a}$

if $\Gamma$ is the current at starting and $t$ the time.

Thus the resistance of our tubes varies as the radius, their self-inductions as the square of the radius, and the time constants as the radius. As regards their coefficients of mutual induction, the quantity $s$ in equation (2) is plainly also the induction per unit current in the tube of radius $r$ passing through any external tube ; thus (2) gives us all the coefficients of self and mutual induction of the tubes. And as regards the coil, if there are N turns of wire in it per unit length of the core, the induction represented by $s$ in equation (2) goes $Nl$ times through the coil, whence

$$(2\pi r)^2 N\mu$$

is the coefficient of mutual induction between the tube and the coil.

The coil may also be treated as a system of concentric tubes, and its self-induction found. If its depth $b$ be very small compared with its radius $a$, the unit current in each wire of the coil, giving a current N per unit length, produces magnetic force of strength $4\pi N$ within it, and induction $4\pi N\mu$, which goes $Nl$ times through the coil over an area $\pi a^2$, making $L_0$ the coefficient of self-induction of the coil to be

$$L_0 = (2\pi Na)^2\mu l \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

provided the permeability is the same throughout the coil opening. Practically, $\mu$ only differs from unity for iron; hence, if the core is of iron and does not fill the coil, (4) requires an obvious correction. To remember (4), observe that $2\pi Na$ is the length of wire per unit length of core, the concentration of the wire, so to speak, thus making the square of the concentration to equal the coefficient of induction per unit length of coil when the inner space is non-magnetic. $L_0$ is what the coefficient of self-induction of the coil would be if every turn had the same radius $a$.

*Self-induction of Coil Circuit.*

Let L be the coefficient of self-induction of the coil circuit, *i.e.*, the amount of induction through the circuit when the unit current flows in it, and there are no other currents (as in the core, for example) to alter the magnetic force. This may be conveniently divided into four parts, say

$$L = L_1 + L_2 + L_3 + L_4 \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

where $L_1$ is that part due to the induction in the core, $L_2$ to the induction in the space between the core and the coil, $L_3$ to the induction *in* the coil, and $L_4$ in the external circuit. $L_4$ is any arbitrary positive quantity. Let $h$ be the magnetic force in the core due to unit current in the coil circuit, that is, $h = 4\pi N$. The induction due to this is $\mu h$, going $Nl$ times through the coil, over an area $\pi c^2$ (section of core), thus making

$$L_1 = \mu h.\pi c^2.Nl = (2\pi Nc)^2\mu l \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Between the core and the coil the magnetic force is also $h$, the area is $\pi(a^2 - c^2)$, and it goes $Nl$ times through the coil as before, hence

$$L_2 = (2\pi N)^2(a^2 - c^2)l \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

In the thickness of the coil, $h$ falls regularly from $h$ to zero, because the current density is constant ; hence if $h_1$ is the magnetic force at distance $r$ from the axis, $h_1$ is given by

$$h_1 = h(a + b - r)/b.$$

At the same time the number of turns *outside* the circle of radius $r$ as it increases from $a$ to $a + b$ decreases regularly, and is therefore given by

$$N_1 l = Nl(a + b - r)/b.$$

Therefore we get

$$L_3 = \int_a^{a+b} h_1 \cdot 2\pi r dr \cdot N_1 l = 2(2\pi N)^2 \frac{l}{b^2}\int_a^{a+b} r(a + b - r)^2 dr,$$

which, worked out, gives

$$L_3 = \frac{1}{6}(2\pi N)^2 bl(4a + b) \quad . \quad . \quad . \quad . \quad (8).$$

We need not stop to put the three parts of L for the coil together, as they will be more useful separately. We have supposed the wires to be of square section with insulating covering of no thickness. The correction is in general very small. The corresponding corrections for the resistance are, however, made in equation (9).

*Resistance of Coil.*

The resistance of the coil circuit is of course indefinite, but an expression for that of the coil alone will be useful, so we give it here, to get rid of preliminary matter at once. The volume occupied by the coil being

$$l\{\pi(a + b)^2 - \pi a^2\} = \pi bl(2a + b),$$

if there are $m$ wires per unit length and depth, so that the former $N = m^2 b$, the whole length of the wire will be $m^2 \times$ above expression for volume, because in a unit of volume there are $m^2$ wires, each of length unity. And to get the resistance of the coil we must further multiply by the resistance of unit length of wire, which last equals its specific resistance divided by its section. The section $= 1/m^2 c_1{}^2\frac{4}{\pi}$, where $c_1$ is the ratio of the radius of the covered to that of the bare wire, so if $\rho_1 =$ specific resistance of the wire, and R the resistance of the coil,

$$R = \pi bl(2a + b)m^2 \cdot \rho_1 \cdot m^2 c_1{}^2 4/\pi = (2Nc_1)^2\rho_1 l(2a + b)/b. \quad (9)$$

*Magnetic Force and Current in Core.*

Let H be the magnetic force at distance $r$ from the axis. It is a function of $r$ only. Let $\gamma$ be the current density at the same place, also a function of $r$. H is parallel to the axis, and $\gamma$ is perpendicular to H and to $r$. Consider a tube of thickness $dr$, carrying therefore a current $\gamma dr$ per unit length of tube, producing magnetic force $4\pi\gamma dr$ within and none outside. $4\pi\gamma dr$ is therefore the amount by which H decreases in passing from $r$ to $r + dr$, hence

$$\gamma = -\frac{1}{4\pi}\cdot\frac{dH}{dr} = -\frac{1}{4\pi}H' \quad . \quad . \quad . \quad . \quad (10)$$

is the general relation between the magnetic force and the current in the core at any place, a special case of $4\pi\gamma = \text{curl H}$ which applies universally.

*E.M.F. and Current in Core.*

Let $e$ be the E.M.F. per unit length in the core at distance $r$ from the axis. By Ohm's law, and by equation (10), we have

$$e = \rho\gamma = -\frac{\rho}{4\pi}H' \quad . \quad . \quad . \quad . \quad . \quad . \quad (11)$$

This E.M.F. is derived entirely from electro-magnetic induction, there being, from symmetry, no difference of potential in the core. (Should the core be placed excentrically in the coil, there would be a potential function to be

Digitized by Google

taken into account by reason of the E.M.F. of induction having a normal component producing displacement outwards.)

*E.M.F. and Magnetic Force in Core.*

The total induction passing through the tube of radius $r$ being expressed by

$$\mu \int_0^r H \,.\, 2\pi r \,.\, dr,$$

and the E.M.F. of induction round the tube being, by the law of induction, the time rate of decrease of this quantity, and also being $2\pi re$, we have

$$2\pi re = -\mu \int_0^r \dot{H}.2\pi r dr \quad . \quad . \quad . \quad . \quad (12)$$

for any value of $r$. We employ, according to a common practice, much shortening expressions, a dot over a symbol to denote time differentiation, and an accent as in (10) and (11) to denote differentiation with respect to the geometrical variable. Putting in (12) the value of $e$ from (11) we have

$$rH' = \frac{4\pi}{\rho} \int_0^r \dot{H} r dr \quad . \quad . \quad . \quad . \quad . \quad (13)$$

one form of the differential equation of the magnetic force. Differentiate (13) with respect to $r$ and we obtain

$$\frac{1}{r}\frac{d}{dr}\left(rH'\right) = \frac{4\pi\mu}{\rho}\dot{H} \quad . \quad . \quad . \quad . \quad . \quad (14)$$

the partial differential equation, a special case of the general equation

$$\nabla^2 H + \frac{4\pi\mu}{\rho}\dot{H} = 0$$

holding universally in pure conductors.

*Coil Current and Core Magnetic Force.*

Whether the core fills the coil or not, the value of H at the boundary of the core fully settles the value of the coil current, for the magnetic force in the intermediate space will be of the same strength from $r = c$ to $r = a$. Hence, if $\Gamma$ is the current in the coil circuit, and therefore in every wire of the coil, and $H_c$ is the value of H at the boundary of the core, we have

$$H_c = 4\pi N\Gamma \quad . \quad . \quad . \quad . \quad . \quad . \quad (15)$$

*E.M.F. in the Coil Circuit.*

If R is the resistance of the coil circuit complete, the total E.M.F. in it is, by Ohm's law, $R\Gamma$. Let E be the impressed force in the circuit, then $R\Gamma - E$ is the value of the E.M.F. arising from electro-magnetic induction. Let this last be $E_1$. Then, by the induction law, $E_1$ = rate of decrease of induction through the whole circuit. Now, the induction through the circuit when there are no core currents is simply $L\Gamma$, where L is the quantity in equation (5), whose parts are later defined. In addition to this, there is the induction through the coil due to the core currents. Since when there are no core currents the magnetic force in the core has the same value throughout, or $H = H_c$, the induction through the coil due to the core currents only arises from the excess of the real magnetic force in the core over its boundary value, and is therefore given by

$$Nl \,.\, \int_0^c \mu(H - H_c)\, 2\pi r dr = 2\pi Nl\mu \int Hr dr - L_1\Gamma \quad . \quad . \quad . \quad (16)$$

where $L_1$ is given in equation (6). The whole induction, say $p$, through the coil circuit is therefore

$$p = (L - L_1)\Gamma + 2\pi Nl\mu \int Hr dr \quad . \quad . \quad . \quad . \quad . \quad (17)$$

and we have $\qquad E - \dot{p} = R\Gamma$

or $$E = R\Gamma + (L - L_1)\dot{\Gamma} + 2\pi Nl\mu \int_0^c \dot{H} r dr \quad . \quad . \quad (18)$$

where it is desirable to get rid of the integration. Put H in terms of H′ by (14), then

$$\int_0^c \dot{H} r dr = \frac{\rho}{4\pi\mu}\int_0^c \frac{d}{dr}(rH')dr = \frac{\rho c H'_c}{4\pi\mu},$$

by integration, which brings equation (18) to the form

$$\left.\begin{aligned} E &= R\Gamma + (L - L_1)\dot{\Gamma} + \tfrac{1}{2}Nl\rho c H'_c \\ \text{or} \quad E &= R\Gamma + (L - L_1)\dot{\Gamma} + \frac{L_1\rho}{2\pi\mu c}\Gamma' \end{aligned}\right\} \quad . \quad . \quad . \quad (19)$$

where in the last $\Gamma$ is to be put in terms of $H_c$ by (15).

Should the core fill the coil, we shall have $L_1 = L_0$, and if, further, the core be of small depth compared with its radius, and there be no appreciable induction in the external circuit, then $L = L_1$ and the second term in (19) goes out altogether, leaving

$$E = R\Gamma + \frac{L_1\rho}{2\pi c\mu}\Gamma' \quad . \quad . \quad . \quad . \quad . \quad (20)$$

as the equation of the E.M.F. in the coil. Its interpretation is easy. For now, with the limitations imposed, the E.M.F. per unit length of wire in the coil is the same throughout, and is the same as the value of $e$ at the boundary of the core and coil, $e$ being given by equation (11); consequently the whole E.M.F. in the coil arising from induction is $2\pi c \,.\, e \,.\, Nl$, which by equations (11) and (15) is the same as the second term on the right hand side of equation (20) with its sign changed. We may also note that the coefficient of $L\Gamma'$ in equation (20) is, by equation (3), the time constant of a tube of unit depth with the mean radius $c$.

*Oscillatory Currents.*

Let there be an oscillatory current in the coil circuit, kept up by an impressed force $E \sin nt$, where E is constant, and $n$ is proportional to the speed, being $= 2\pi\nu$, if $\nu$ = number of complete waves per second. At starting, the current will not be simple harmonic, but in a very short time, usually a small fraction of a second, the whole system of magnetic force and current will settle down to vary with the time according to the simple harmonic law, though the coil current will not be in coincident phase with the impressed force, nor with the core currents. But the magnetic force H is a function of $r$, therefore put

$$H = H_1 \sin nt + H_2 \cos nt \quad . \quad . \quad . \quad . \quad (21)$$

where $H_1$ and $H_2$ are functions of $r$ only. To find their form, insert the right side of equation (21) in equation (14), which H must satisfy. We get

$$\left.\begin{aligned} \frac{1}{r}\frac{d}{dr}(rH'_1) &= -xH_2 \\ \frac{1}{r}\frac{d}{dr}(rH'_2) &= x + H_1 \end{aligned}\right\} \quad . \quad . \quad . \quad (22)$$

where $x = \dfrac{4\pi\mu n}{\rho}$; from which we find that both $H_1$ and $H_2$ are subject to

$$\frac{1}{r}\frac{d}{dr}r\frac{d}{dr}\frac{1}{r}\frac{d}{dr}r\frac{d}{dr}H_1 = -x^2 H_1 \quad . \quad . \quad . \quad . \quad . \quad (23)$$

To obtain a suitable series, put

$$H_1 = A_0 + A_1 r + A_2 r^2 + \ldots,$$

insert the series in (23), perform the differentiations, and equate the coefficients of the different powers of $r$ to 0 separately. We find that all the odd A's are zero, and that

$$H_1 = A_0 M + A_2 N,$$

where M and N are functions of $r$ given by

$$\left.\begin{aligned} M &= 1 - \frac{x^2r^4}{2^2 4^2} + \frac{x^4r^8}{2^2 4^2 6^2 8^2} - \frac{x^6r^{12}}{2^2 \ldots 12^2} + \ldots \\ N &= \frac{xr^2}{2^2} - \frac{x^3r^6}{2^2 4^2 6^2} + \frac{x^5r^{10}}{2^2 \ldots 10^2} - \ldots\ldots\ldots \end{aligned}\right\} \quad . \quad . \quad (24)$$

$H_2$ is of course the same in form as $H_1$, say with constants $B_0$ and $B_2$. But the equations (22) have to be separately satisfied. This requires that $A_0 = -B_2$ and $A_2 = -B_0$, which makes (21) take the form

$$H = (AM + BN)\sin nt + (AN - BM)\cos nt \quad . \quad . \quad (25)$$

where M and N are given in (24), and A and B are two arbi-

Digitized by Google

trary constants (the former $A_0$ and $A_2$). We should note that M and N are subject to

$$\left.\begin{aligned}\frac{1}{r}\frac{d}{dr}(rM') &= -xN' \\ \frac{1}{r}\frac{d}{dr}(rN') &= +xM'\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (26)$$

which relations are very useful in transformations.

The functions M and N are of the oscillatory character. Oscillatory functions are always turning up in mathematical physics, even in questions having nothing to do with vibrations. M and N are related to Fourier's function for the cylinder, or Bessel's $J_0(z)$ function, where

$$J_0(z) = 1 - \frac{z^2}{2^2} + \frac{z^4}{2^2 4^2} - \ldots$$

by the following equations:—

$$\left.\begin{aligned}J_0(r\sqrt{xi}) &= M - Ni \\ J_0(r\sqrt{-xi}) &= M + N^i\end{aligned}\right\} \quad . \quad . \quad . \quad (27)$$

where $i$ stands for $+\sqrt{-1}$, from which we have

$$\left.\begin{aligned}M^2 + N^2 &= J_0(r\sqrt{xi})\, J_0(r\sqrt{-xi}) \\ M'^2 + N'^2 &= J_0'(r\sqrt{xi})\, J_0'(r\sqrt{-xi})\end{aligned}\right\}$$

&c., and many other relations connected with energy properties. But it is easier to work with M and N than with the corresponding imaginary Bessel's functions.

In equation (25), where H is a known function of $r$ and $t$, we have the solution for the magnetic force in the core, except as to two constants which fix the amplitude and the phase. By (15) the coil current is known in terms of the core boundary value of H, and by (10) the core current is known.

The amplitude of H is the square root of the sum of the squares of the coefficients of the sine and cosine in equation (25). Denoting the amplitude by (H) we have therefore

$$(H)^2 = (A^2 + B^2)(M^2 + N^2) \quad . \quad . \quad (28)$$

and if (Γ) be the amplitude of the coil current,

$$(\Gamma)^2 = \frac{A^2 + B^2}{(4\pi N)^2}(M^2 + N^2)$$

where the boundary values of M and N must be used.

(TO BE CONTINUED.)

## THE COST OF TRANSMISSION BY ELECTRICITY.

In a recent account of the proposals now under consideration for supplying motive power from the River Rhone to the City of Geneva we spoke of a work dealing with the comparative cost of the various systems of transmitting power, of which the author is Herr A. Beringer, of Berlin. Of this work, which obtained a prize offered by the Electro-Technical Society of Berlin for a treatise on this subject, we are able now to give a short account, taken from a notice in the *Proceedings* of the Architects' and Engineers' Society of Hanover. The book, though extending to 240 pages, does not cover the whole of the subject, being in fact confined almost exclusively to the transmission of power available at a given spot to another fixed position at a distance. The questions of electric railways, and of the distribution of electrical energy when thus conveyed, are scarcely touched upon. In consequence the transmission of power by electricity scarcely has justice done to it, because its advantage lies more particularly in the fact that conducting wires can be easily shifted as required, that any number of bends or corners occasion no difficulty and no loss, and that the taking off of power at different places in rapid succession presents no obstacles. In addition, the section of the conductor required is very small, as is also the weight and volume of the machines by which the electrical energy is again transformed into mechanical energy. The three methods of transmission with which electricity is here compared are those of water-pressure, of compressed air, and of wire ropes. The special problem considered is to determine the cost of one horse-power conveyed to the point of application, when the total energy thus conveyed and the distance traversed are given. This cost has, of course, different values according to the price to be paid for the horse-power at the initial point before it is transmitted. On this head the author adopts generally the values given by Professor Grove as the result of a careful investigation. These values are expressed in German pence, which are almost exactly equal to the hundredth part of a shilling. We shall take them as being exactly equivalent to these, and therefore the results can be given in English money by the simple process of dividing by 100. We have, however, taken the subsequent step of multiplying by 12, so as to give them in pence, the most usual English unit. In cases where water-power is the source of our energy it is obvious that its value in different places differs so greatly that an average price can scarcely be laid down. The author, following Meissner in his work on hydraulics, assumes for this the value of $\frac{3}{5}$d. in German pence (·0067 of a shilling or ·08d.) per horse-power per hour.

The theory of the different modes of transmission is merely so far treated as is necessary for the practical appreciation of the subject. In many cases theory is unable to take into account, wholly or partially, a number of circumstances which greatly affect the result, and hence the author relies chiefly on the data of actual experiments, a fact which makes his work of more value.

Commencing with electricity, the author sets forth the theoretical principles laid down by Frölich and by Sir William Thomson as to the losses in energy, and the most favourable dimensions for the conducting wires. It is important to observe that with an equal strength of current, and an equal price for driving machinery, a copper conductor is only about 16 per cent. dearer than one of iron. For the intensity of current allowable in transmission of power, the author assumes the value of 1,500 volts, which would seem to be unduly high. Certainly with electrical railways, which hitherto have given the most satisfactory examples of this mode of transmission, about 300 volts is the highest intensity aimed at in practice. It is unfortunate that the author does not take into consideration the losses which are caused by the high velocity of the dynamo machines. At the place where the current is generated it is usually necessary to provide machinery for passing from a moderate to a high velocity of rotation, and at the place where it is used similar machinery for passing from a high velocity to a moderate one. In both cases there is a considerable loss of energy.

Coming next to hydraulic power, the net efficiency of such transmission depends on three factors—namely, that of the pressure pump, that of the conducting pipes, and that of the hydraulic motor. The first of these may be taken on an average at 90 per cent., and the third at 60 per cent. for small and 75 per cent for large powers. The second varies according to the distance traversed. Formulas are given to determine, from the losses by friction and the prime cost, the most favourable dimensions for the pipes; and it appears that these dimensions will be very different according as the power to be transmitted is cheap or dear at the starting point.

With regard to compressed air it is assumed that the variations in temperature, which here form the chief obstacle, are diminished by the well-known process of injecting spray, this being the only condition under which this form of transmission is considered to be generally applicable.

Lastly, with regard to wire ropes, it appears that the efficiency of this apparatus is very satisfactory up to a distance of one kilometre (·6 of a mile), but falls off rapidly as the distance increases beyond this.

The cost of the machine, connections, &c., required in the different cases is carefully selected from approved sources, and forms a good basis for determining the most favourable kind of power transmission in any particular case. The general results so deduced are given in Table I.

It will be seen from Table I. that for small distances the wire rope system is far in advance of all the others as regards efficiency, but for very long distances compressed air and electricity give the most favourable results. It must, however, be remembered that it is only in a few cases that the efficiency of the system forms the only or principal ground for deciding upon its use. The tables which follow show that the transmission of power is of special advantage

Digitized by Google

when the question is to satisfy demands for small quantities of power at various points situated at a considerable distance from each other. This is exactly the case of a town where a number of small industries are practised. Such industries have generally to contend with a want of sufficient capital, and therefore work under unfavourable conditions; hence it is of much importance to compare the cost of laying down the various systems of power transmission with the cost of a separate engine put down at each of the places where it is required. For this purpose Table II. becomes of much interest.

The prime cost per horse-power for an independent engine would be on an average as follows:—For a steam engine of 5 horse-power, £50; of 10 horse-power, £45; of 50 horse-power, £20. For a gas engine of 5 horse-power, £75; of 10 horse-power, £60; of 50 horse-power, £40. This table shows that it is in comparatively few cases that a system of transmission of power, at least to any considerable distance, is cheaper in first cost than the putting down of an independent

TABLE I.

EFFICIENCY OF VARIOUS MODES OF TRANSMISSION.

| Distance of Transmission. | | Trans. by Electricity. | Transmission by Water. | | Transmission by Air. | | Transmission by Ropes. |

engine; hence such a system can in general be only adopted when an excess of power is forthcoming at some particular place, or when from natural circumstances (as in mines, tunnels, &c.) the laying down of an engine on the spot is attended with difficulty. The table further shows that in the transmission of power to greater distances, in which the cost of the connections becomes important, the electrical system distinguishes itself by its greater economy. On the other hand, for short distances wire ropes and water pipes offer a cheaper solution of the problem. The conditions, however, are much more favourable for electrical transmission when the Cost of Working of the various systems comes under consideration. This is given in the two Tables III. and IV.

Table III. shows that in transmitting to 5 kilometres the power generated by a large steam engine all the systems are tolerably on an equality. Up to this point the wire rope gives in all cases the most favourable and compressed air the least favourable result. If as much as 10 horse-power is required at one place, it would appear that a special steam engine on the spot would have the advantage in economy, but even to a distance of 8 kilometres transmission by electricity appears to be cheaper than the putting down of a gas engine at the point of application. Table IV. gives the working cost per horse-power per hour in transmitting power generated by water, costing originally only 0·08d. per horse-power per hour. It is probable that the assumption here made as to the cost of a horse-power obtained from water-power is in general too low. The table is, however, of great importance as showing that where cheap water-power is available it may be transmitted by electricity even to distances of 20 kilometres with considerable advantage over power as generated on the spot. Here also up to distances of 3 kilometres the wire rope shows greater economy than electricity, this being due to the high cost of electric machines. It must, however, be remembered that the energy generated by

electricity may in many cases be employed at the same time for other purposes, such as for lighting, or chemical processes; and this may be done at times when the requirements in mechanical work are small. Hence in many cases the preference should be given to that means of transmission whenever the problem is to make the best utilisation of cheap water-power. Hence it follows that electrical energy has an almost unlimited application, provided the distance of transmission is not very great.

The special point brought out by the whole inquiry is the necessity of providing electrical machines of the cheapest and most handy form possible, and such as are capable of converting in the most advantageous manner the electricity sent from the central station into mechanical energy as required for ordinary purposes.

## THE POSTPONEMENT OF SIXPENNY TELEGRAMS.

The delay which is now definitely announced as certain to occur in reducing the tariff for inland telegrams is not wholly to be regretted, even from the point of view of those who were the warmest advocates of immediate reduction. The Chancellor of the Exchequer in his Budget speech stated that it would be inexpedient—in other words financially impossible—to introduce the sixpenny tariff at the date orginally fixed, namely, next October, and nominally postponed it until the following August, although not pledging the Government even to the last-named date.

Certain of Mr. Childers's critics have professed surprise at the postponement, and even accused him of trifling with the subject. Without questioning the sincerity of the accusers, we may remark that their complaint comes a little late. The trifling, if trifling there was, occurred in the earlier stages of the discussion, when a vote which was almost accidental, and certainly not strongly supported, was accepted without due consideration of the cost, or even of the preparations necessary to carry the vote into effect. The result was, that the Budget speech of last year treated the subject as if it were only a matter of money, and left out the element of time altogether. If this was not a trifling error it was a foolish one, and it had to be speedily confessed by a postponement, the practical necessity for which was obvious from the first, but which evidently had been overlooked all along by the theoretical promoters of sixpenny telegraphy.

When at length it came to be understood that a vast extension of the telegraph plant, and a proportionate augmentation of the staff would be needed to meet the expected increase of traffic, the delay till next October was accepted with as good a face as could be put on it. One more lesson had still to be learnt, and the Parcels Post has enforced it. Not only must there be a large outlay in the first instance, but there must be a serious loss of revenue for an indefinite period subsequently. The outlay, or a portion of it, is being spent now; but the loss cannot be faced yet awhile, because the Post Office income has already suffered considerably by a novelty initiated, not by Parliament, but by the present Postmaster-General, who has gone into the parcels delivery line. The deficit in this case is actual; whereas the estimated loss by the proposed sixpenny tariff was too remote and too indefinite to awaken serious misgivings until now. It is unfortunate that the carriage of parcels by a State department has not been a financial success; but if its failure should help to fortify the position of those who predict a possibly more serious failure for the other experiment, the country may be the gainer in the end, for there is now a better chance of the tariff being finally framed on a sound basis.

In the interval which has elapsed since the reduction of the tariff was decided upon there has been time to calculate the loss likely to be sustained respectively by the several schemes put forward. The result apparently has not been encouraging, otherwise one or other of the suggested tariffs would have been proceeded with. It is publicly stated that no decision has yet been arrived at as to the kind of tariff we are to have. A telegram is to cost only sixpence; that is all we know at present. What the telegram is to be, whether its addresses are to be free or taxed, whether limited in length or unlimited, whether the text is to have ten words or twenty, are matters still undefined. We may safely assume, therefore, that the most profitable of these several schemes, or rather the one entailing least loss, will, in fact, cause a diminution of net revenue sufficiently serious to prevent any alteration for some time to come. To any one acquainted with the subject it is well known that one of these schemes, that of charging for every word transmitted either so much per word or so much per telegram, would be immensely less costly than the alternative proposals embodying free addresses; yet unless the Government are gratuitously postponing the change until they can concede the most wasteful of these schemes, which we can hardly suppose to be the case, it may be safely inferred that the least wasteful one is found to be more costly than was at first supposed. The advocates of sixpenny telegrams will do well to bear this fact in mind, and to limit their demands to a reasonable reduction of the tariff if they hope to obtain any reduction at all.

The delay will probably have the effect of moderating these demands, and of facilitating the desired reform at no very distant date. But this is not all; had the alteration taken place as at first contemplated, with hardly any preliminary provision, there would certainly have been a block of traffic, resulting probably in a permanent deterioration of the service. Traffic under a popular tariff is pretty much what traffic managers choose to make of it; and it is not likely that facilities for rapid transmission will be increased beyond the limits of possible profit. In other countries we observe this as one effect of a system which is too cheap to be very well served. Here we have one that will compare favourably with the best systems in the world; but which, if precipitately changed, might be lowered to rank with the worst. Fortunately sufficient time will now be allowed to complete extensions, train

Digitized by Google

operators, and enlarge offices, so that when the change comes it may be met with confidence, and the increased traffic disposed of with as much celerity and as little complaint as are the rule at present. This at all events may be looked for if wise counsels prevail, and the tariff itself is framed on equitable principles, but not otherwise.

## OUR ANNUAL MEETING.

Since the resuscitation of *The Electrician* it has been customary for the proprietors and contributors to meet together at least once a year for an evening's social intercourse. The annual dinner was again held at the Criterion on Friday evening, April 25. It is impossible, however much we may wish it, so to arrange an evening that all contributors can be present. The names of Professor Adams, F.R.S.; Professor O. J. Lodge, Dr. Gore, W. R. Browne, Oliver Heaviside, Magnus Volk, and others will be missed from among those present. Mr. John Pender, M.P., presided, with Sir James Anderson as vice-chairman. The other gentlemen present were—Lord Bury, Mr. Cartwright, M.P.; Professor D. E. Hughes, F.R.S.; Mr. R. E. Crompton, Mr. Desmond FitzGerald, Mr. W. W. Beaumont, Mr. T. H. Blakesley, Mr. G. Kapp, Dr. Shettle, Mr. F. C. Webb, Mr. Payton, Mr. John Pender, jun.; Mr. E. C. Rimington, Mr. W. H. Parker, Mr. J. F. Moulton, F.R.S.; Mr. B. Smith, Mr. J. Laister, Mr. W. H. Preece, F.R.S.; Mr. H. Saunders, Major Flood Page, Mr. J. W. Swan, Mr. J. T. Sprague, Mr. C. H. W. Biggs, Professor W. Garnett, Mr. E. Graves, and Mr. L. Floersheim. It may amuse some readers if for once we give a list of the "toasts," which were as follow:—"The Queen and the Royal Family" was proposed by the Chairman, "The Houses of Parliament" by Mr. J. W. Swan, Lord Bury responding for the House of Lords and Mr. Cartwright, M.P., for the House of Commons. Lord Bury proposed "Her Majesty's Telegraph Department," to which Mr. E. Graves responded. Then came "Success to Submarine Telegraphy," by Mr. J. F. Moulton, to which the Chairman replied. "The Learned Societies" was proposed by Mr. J. Laister, and replied to by Professor Hughes, F.R.S., and Mr. W. W. Beaumont, A.M.I.C.E. Professor W. Garnett gave "Success to Electric Lighting," to which Mr. R. E. B. Crompton replied. "Success to *The Electrician* and Our Hosts" was given by Mr. W. H. Preece, F.R.S., and responded to by Sir James Anderson. "The Staff and the Contributors" was proposed by the Editor and replied to by Mr. D. G. FitzGerald and Mr. J. T. Sprague, concluding with "Our Visitors," proposed by the Chairman and responded to by Lord Bury.

Mr. Pender took occasion to very earnestly impress upon the scientific gentlemen present—and through them the men of science who were absent—that the commercial world was ready and willing to aid in the introduction of *bonâ fide* inventions; but a dread was in men's minds in relation to all that pertained to mere company-mongering. The development of submarine telegraphy was due to the able man of business being provided with the necessary apparatus by the man of science, and although some twenty years only had elapsed since the real initiation of submarine telegraphy, some £32,000,000 were invested in 100,000 miles of cable, giving an annual return of about £3,000,000. This work was illustrative of the manner in which private enterprise catered for the wants of the world. The work had revolutionised political, social, and commercial manners. Yet he believed we were but on the threshold of the work connected with applied electricity, a vast future lying before us, large enough to absorb all the productive work of scientific men for many years to come.

It may also be mentioned that the general opinion of those present in regard to electric lighting was that the greatest depth of depression had been reached, and there were prospects of steady progress in view.

We think we shall be correct in saying that a very pleasant evening was spent, and that the excellent catering of Messrs. Spiers and Pond was duly appreciated.

# CORRESPONDENCE.

## THE THEORY OF MAGNETISM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read the very interesting letter of Dr. Shettle upon the "Theory of Magnetism," but I find that he credits me with views entirely opposite to those I wished to be conveyed in my numerous papers upon magnetism. He says:—"If I interpret Professor Hughes aright, he considers magnetism, like heat, a mode of motion." Perhaps I have not clearly stated what I mean by the rotation of a magnetic molecule whenever any change in the external evident magnetism of a bar of iron occurs. The axis upon which it rotates would be central and perpendicular to its poles. An ordinary compass needle conveys exactly the idea I wish to illustrate. If we had an infinite number of such needles, and their north poles were all pointed symmetrically in one direction, then we should have a strong evident north polarity at one end of the series, the opposite end having the opposite pole.

One can perfectly imitate this with magnetised steel beads, and thus observe visually the mode of rotation that will produce invariably all the known effects of external magnetism; but I have not found that any magnetic effect can be produced by rotating a magnetised sphere, bar, or beads when rotated upon an axis passing through their polarities. If there is any such motion it remains to be proved. The only motion that I believe is demonstrable is that of partial rotation when a change occurs in the magnetic condition of an iron bar.

In my paper to the Royal Institution I said, in regard to magnetism as a mode of motion:—"Let us take this soft iron rod; it seems quite neutral, although we know that the earth's magnetism is trying to rotate its molecules to north polarity at its lowest extremity. We now put it in mechanical vibration by striking it gently with a wooden mallet; the molecules at once rotate, and we have the expected strong north polarity. Let us repeat this experiment by employing heat, and here again, at red heat, an equal strong north polarity appears. Again we repeat, and simply pass an electric current, of no matter what direction; again the same north pole appears. Thus these forces must be very similar in nature, and may be fairly presumed to be vibrations or modes of motion, having no directive tendency except a slight one, as in the case of electricity. For the same three forces render the rod perfectly neutral, even when previously magnetised when placed in a longitudinally neutral field as east and west. Motion of the molecules gives rise to external magnetism to a rod previously neutral, or renders it neutral when previously magnetised; in other words, it simply allows the molecules to obey an external directing influence. The only motion, therefore, is during a change of state or polarity. If there is constant polarity there is no consequent motion of the molecules; in fact, the less motion of any kind that it can receive the more perfect its retention of its previous position; consequently, constant magnetism cannot be looked upon as a mode of motion. Neither vibratory nor rotary, it is an inherent quality of each molecule, similar in its nature to its chemical affinity, cohesion, or its polar power of crystallisation. A molecule of all kinds of matter has numerous endowed qualities; they are inherent, and special in degree to the molecule itself. I regard the magnetic endowed qualities of all matter or ether to be inherent, and that they are rendered evident by rotation to a symmetrical arrangement in which their complete polar attractions are not satisfied."

I find also that Dr. Shettle draws conclusions from my late paper to the Royal Society somewhat different to those I wished to convey, the object of that paper being to show the molecular structure of a bar of iron whilst under the influence of a directing cause, and also to show how this structure became externally neutral upon its cessation. I must acknowledge that my paper is not written clearly. The experiments, however, seem decisive on this point, and to my mind are an additional proof of the experimental truths of my views previously expressed.

There are essential points of difference in the theoretical

Digitized by Google

view of Dr. Shettle and myself, but I am sure we are all much interested in his researches, which I hope he will continue.—Yours, &c., D. E. HUGHES.

## AN ELECTRIC TELL-TALE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have received a copy of the preliminary prospectus of a company called Webb's Electric Calculating and Check Till Company (Limited), which purports to be formed for the purpose of acquiring the invention known as Webb's New Automatic Electric Tell-Tale Till. In the prospectus it is stated that Mr. Webb's invention "has received the high commendation of no less eminent electricians than Dr. Siemens and Professor Sylvanus Thompson."

Will you kindly allow me to state, firstly, that I have never expressed any opinion either in favour of or against Mr. Webb's invention, for the simple reason that I have never seen anything of it; and, secondly, that the use of my name by the persons responsible for the issue of the prospectus is entirely unauthorised by me?

The prospectus also states that "this remarkable invention" makes "ample provision against dishonest and collusive devices." If this were so I should not need to trouble you.—Yours, &c., SILVANUS P. THOMPSON.

University College, Bristol,
April 28, 1884.

## HEATING EFFECTS OF ELECTRIC CURRENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As Professor George Forbes has rightly assumed in his letter to you of April 21, I was unaware of his results of 1882, and it would of course be far from my wish to ignore what he has done. The proof of his recent paper to the Society of Telegraph Engineers only reached me by post on the morning of April 23.

I should remark, however, that my letter to you on "Heating Effects of Electric Currents" was not meant to be exhaustive, and only intended to give as brief an account as was possible of a few experimental results which it seemed important should be read along with those announced by Mr. Preece in his paper to the Royal Society.—Yours, &c.,

J. T. BOTTOMLEY.

The University, Glasgow, April 27, 1884.

## ELECTRIC CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Allow me to make a correction in my letter appearing in your issue of the 26th April.

The formula used should be

$$S = \frac{a\,l\,C\,100}{p\,E},$$

where $p$ = percentage of E.M.F. lost in the conductor.

I also omitted to say that the table was computed for currents at 100 volts.—Yours, &c., N. M. ARNOT.

London, 28th April, 1884.

## THE ELECTRIC LIGHT IN OUR HOMES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Amongst the instances of domestic electric lighting, my own, which has now been working since the commencement of this year, has so far been a great success.

My installation was put down by Mr. Cunnington, of the Edison and Swan Company, who has exhibited great care in the work. I have twenty-two 37-volt Swan lights, twenty-two Sellon-Volckmar accumulators, a 10-light Victoria dynamo, and a one horse-power Tangye gas engine, which light all the principal rooms, hall, &c. The lights, enclosed in ground glass shades from Verity's, are generally suspended by simple wooden brackets from the picture rods round each room. The accumulators are placed in a cellar, and the engine and dynamo are outside the house, in what was formerly a coal shed.

The economy of my Tangye engine, as compared with an Otto, I have not been able to ascertain; but, undoubtedly, in a town house, the silence of an Otto would be preferable. One important point, never mentioned by gas engine makers, is the great cost of the sperm oil, &c., which is necessary.

The ease of lighting, the steadiness and softness of the light, together with the cleanliness and absence of heat, will warrant the slight extra expense above that of gas.—Yours, &c.,

WALTER PALMER.

Westfield, Reading, April 28, 1884.

## THE MAXIM-WESTON COMPANY IN ENGLAND.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: My attention has been called to a letter in yours of 26th inst., under the signature "Hiram S. Maxim," the contents of which, as far as they relate to this company and myself, are in every particular untrue.

Your last correspondent regarding this Company I am informed is now in prison for libel, and so you will excuse my caution to you against publishing, under irresponsible signatures, libellous matters.—Yours, &c., H. WATT.

32, Queen Victoria-street, London, E.C.,
30th April, 1884.

[Mr. Watt's caution to us is not needed. He is quite mistaken about our last correspondent. We always regret to have to call attention to the mistakes of individuals, but it is sometimes necessary to do this for the public good. Till we received Mr. Maxim's letter, we imagined him to be in the pay of the company, and have reason to suspect that we were not alone in our opinion. That the company cannot afford to give these high salaries is also a matter in which we are justified in expressing our views.—ED. *E.*].

Mr. Maxim has requested us to publish the following letter which has been addressed to him:—

Hiram S. Maxim, Esq.,
57D, Hatton-garden, E.C.

Dear Sir: In reply to yours of yesterday's date, I have read the letter in *The Electrician* of the 26th inst., and I feel bound to say it is true what you say; and in reference to Mr. Watt's agreement with the Maxim-Weston Electric Company, I believe it was signed and sealed in the absence of Mr. Kabath, who was at the time in Paris, and who, on his return, sent in his resignation as a director of the company in consequence, as he considered that the position of the company did not justify an agreement for three years at such a high salary as £600 per annum. I did send notices to the financial papers of your appointment as consulting electrician, as I considered that you were appointed as such. I believe the statements you make in the said letter are all virtually correct and true.

Yours truly,
J. W. Bryan,
late Secretary of the Maxim-Weston Electric Company (Limited).

23, Tunstall-road, Brixton, S.W.,
April 29th, 1884.

## THE LIGHTING OF THE LEEDS MUNICIPAL BUILDINGS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The paragraph in your issue of the 26th April, referring to the "Opening of the Leeds Municipal Buildings," is so extraordinary a version of the facts of the case that we were at first disposed to treat it as a joke. Seeing, however, that with some of your readers it is calculated to injure our reputation as implying that we had failed in our contract for lighting these buildings, we beg to state that we had at the time of the opening of the municipal buildings nearly a month unexpired of the time allowed in the contract. The subjoined

Digitized by Google

letter from the chairman of the Electric Lighting Committee represents the facts of the case, and being from an authority from whom there can be no appeal, we do not think it necessary to add one word by way of disclaiming the obligation you represent us as being under to Mr. Crompton, or to detract from the magnanimity imputed to him.—Yours, &c.,

PATERSON and COOPER.

St. Paul's Telegraph Works, 76, Little Britain,
London, E.C., April 30, 1884.

"To Paterson and Cooper.

"Opening of the Leeds Municipal Buildings.

"A paragraph in *The Electrician* of the 26th calls for some explanation.

"There was no electric lighting in the municipal buildings and no contract had been entered into for them to supply the light in the Victoria Hall, where it was shown at the mayor's banquet.

"Crompton and Co. had supplied this light at the recent musical festival; the fittings and engines had remained undisturbed, and were ready to work at almost a moment's notice, and at no material cost. It was a matter of good taste and good feeling towards the mayor. Crompton and Co. are entitled to the credit of this, but no discredit rests on Paterson and Cooper, who had no connection at all with the Victoria Hall. I am respectfully,

"(Signed) George Tatham,
Chairman of the Electric Lighting Committee, Leeds.

"Town Hall, Leeds, April 29, 1884."

## "INCANDESCENCE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Could you give me a little light in the following? A certain degree of incandescence in a lamp filament indicates a certain number of candles per, say, 746 watts of energy expended in producing that incandescence, or, in other words, a certain economy of light production, the carbon filament resistance being $x$ ohms. If $r$ be not $x$, but something less or more, the economy is of course affected, increasing as $r$ becomes greater, and decreasing as $r$ lessens, or inclines to that lowness of resistance usually termed "short circuiting." Economy of light production is also affected (although in my opinion to but a slight degree as far as practical purposes are concerned) by the form of the section of the filament. Laying aside, however, these considerations, and taking the case of one individual lamp only, let us again say that the economy depends upon the degree of incandescence. Now, is there any method of permanently recording a particular degree of incandescence? Let us call a particular stage of incandescence $a$. This has been found, let us say, to be the "economic mean" at which a particular make of lamp should be run under average conditions as to cost of power and cost of renewals. Now take an incandescent lamp of another maker. How is the observer to recognise this particular degree of incandescence $a$ in this other lamp? Dependence on the eye is but little better than guess work, and not to be relied on even when the two lamps are burning in juxtaposition at the same time, it being a very difficult matter, for example, to decide whether a Swan lamp with looped carbon and an Edison lamp with curved carbon are or are not at the same degree of whiteness even when viewed side by side. Can the spectroscope not aid us? I am rusty on the subject of spectrum analysis, but I think I am right in saying that the spectroscope would give the same lines whatever the degree of incandescence in the carbon filament, but that when the latter was at orange or dull yellow the red portion of the spectrum would be more pronounced than when the filament was emitting an intense white light, when the violet portion of the spectrum would be most marked. Would it be possible and practicable to secure photographs of the spectrum at various stages of incandescence which would serve as records to be used for comparison with other photos taken from another lamp, and thus to settle whether the observed incandescence of the one lamp was inferior, superior, or equal to that of the second?

I have not seen this idea mooted before. Possibly you can say something on the subject, or if you care to put part of the above in type, good and well.—Yours, &c.,

A. D.

[Perhaps Mr. Wright will have time to say something on this matter, as we know he has given it a considerable amount of attention.—ED. *E.*]

## SMALL DYNAMO.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I have been successful in making two or three machines about the size of your correspondent's, may I venture to suggest that "W. H." will find 4lb. No. 18 C.C. wire insufficient to saturate his field-magnets, on account of the small sectional area which that gauge of wire possesses? I have not a doubt that if he replaces the existing wire with 7lb. double C.C. the maximum effect will be obtained, but before doing so I should recommend him to try what result can be got by coupling up the machine in simple shunt. Nevertheless, the best results seem to be obtained when armature and field magnets have about the same resistance (say 1·5 ohm). There are several points which require considerable care in order to make a good dynamo. Most amateurs either get the resistances greatly out of it, or manage to short-circuit the machine in the act of coiling.—Yours, &c.,

E. T. N.

## OVERHEAD AND UNDERGROUND TELEPHONE WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your correspondent, "Telephonist," wrote such a scant reply to my first letter that I ought not to be much surprised at what seems to be his final flutter in last week's *Electrician*. I am, however, very much surprised. He repels the soft impeachment that he might possibly be writing at the telephone company's instigation, and I am now quite satisfied he is no true friend of theirs, or he would have attempted to reply to my letters in some more serious fashion.

The United Telephone Company will scarcely thank "Telephonist" for his puny advocacy, beginning with faint praise, and ending with such a sudden retreat that in his final sentence he forgets that the readers of *The Electrician* are witnesses that he has not answered one quarter of my statements of facts and inferences.

The United Telephone Company boast of the scientific witnesses they intend to array against the public before the parliamentary committee (if their little Bill does not collapse before it gets that distance). Their conduct—both in in its commercial and technical aspects—seems to show that they look upon scientific witnesses as stalking horses or decoys, to be bought at so much per dozen, to be used by turns to screen themselves and to allure their game, until, having secured the unearned confidence of the public, the advice of the former and the interests of the latter will be equally ignored.

I do them no wrong in speaking thus, as I will presently prove. But if they should even then think so, let them point out where. They have flung their flouts and sneers in the face of the Postmaster-General, and called him "dog in the manger."

In the columns of *The Times* and the *Pall Mall* they have done so to persuade the public that they—the United Monopolists—are the real Simon Pure. But in the columns of *The Electrician* I will now show that they know they are groping in the dark, and yet although they know the columns of electrical journals are open to them, something or other seems to prevent them from comparing notes freely and in friendliness with their numerous *confrères* in the electrical world, who would be only too glad to help them out of the wood. They may repudiate

Digitized by Google

that mataphor, but they cannot deny the feeling of helplessness that almost paralyses them when they find their customers compelled to give up the telephone as useless. Your correspondent, "Telephonist," gives utterance to the common cry of telephonists in distress when he refers to that *bête noir* "induction." Induction is, no doubt, a very troublesome reality.

All the more reason why it should be thoroughly investigated, especially as the company are asking Parliament to grant them power to do that which they have been continually saying for the last four years is an impossibility, owing to the insurmountable difficulty caused by induction. Their stereotyped reply to complaints of their *clientèle* when objecting to their conversations being heard on other lines by strangers seems to be to the same effect. So that many people are thoroughly disappointed with the telephone, and are led to believe that the publicity given to their private conversations (sometimes important business secrets) is an inseparable evil connected with an otherwise invaluable invention. If the company, therefore, intend (contrary to "Telephonist's" assertion) to put wires underground in accordance with the powers and conditions specified in the Bill, what will they do to prevent the present confusion being "worse confounded?" or I might say, on the authority of their vice-chairman, "sixteen" times worse confounded.

Well, they may perhaps suspend their private judgment whilst they make a more or less extensive practical experiment on the principle of "heads I win, tails you lose." It is well known that the United Telephone Company set little value on scientific experiment, however much the scientific process may be modified by "rule of thumb." Sheer ignorant, happy-go-lucky experiment suits better; but best of all is they think to adopt the latter principle as an article of faith, and embody it in the permanent routine of business.

I will show how this principle is in operation at present, and then how it will operate if they get their Bill passed.

By leave of "Telephonist" I will postpone the "research" that he advises on the subject of "induction," and with his own sentence as a starting point I will show how the company deal with the subject. "Telephonist" says: "I have only to state (what is really a most obvious fact, known to any one having even only a slight practical knowledge of telephony), that where two wires are laid close together, a current travelling through one of them will inevitably produce a current, and a reproduction of the speech through the other (a fact which your correspondent will not require to make a very deep research to ascertain), and I feel sure he will not require to further prolong this correspondence."

Several points in this sentence tempt me to a little interesting diversion. Although a long sentence it is in some respects felicitous, and it is a curious fact that the central word "inevitably" suggests and includes the whole gist of the controversy. But for that word I could not object to the sentence as a fair statement of a common-place proposition, and yet without that word the whole letter would have been practically pithless. I am also sorry to add that either with that word or without it the statement is too utterly inaccurate to serve the purpose intended.

I will try to convince "Telephonist" that his mental horizon is capable of extension if he will follow me into a few of the ramifications into which his statement naturally leads. I will begin with two propositions sufficiently defined to prevent the confusion that his own proposition might lead to.

1st. Where two insulated wires are laid close together, and each wire is, say, twenty times the length, and of a resistance equal to that in the instruments at both ends, then speaking through one of those wires may be heard through the other wire, but the voice will be diminished to about one-fourth of its volume, and provided that the insulation of all the conductors is perfect, then the effect will be at all times "inevitably" in the same proportion.

2nd. Where two insulated wires are laid close together, no matter what may be the respective lengths, if the insulation is not waterproof and if a small portion, say the hundredth part, of each conductor is affected by wet or damp, then the wire adjoining the one which the speaking current traverses will be acted upon in some instances as effectively as if the whole length were subject to induction, as in the former case. But in the latter case the effect on the adjoining wire is from leakage instead of induction; hence the voice received through a wire influenced by the medium of leakage through damp from the wire conveying the original current is sometimes stronger or of greater volume than is the voice received through the instrument in uninterrupted metallic connection with its originating source. It ought not to be difficult to get these two features of the question well separated, yet well impressed on the mind. The ever varying mixture of the two classes of phenomena will then be less bewildering. There is another correlative fact, however, which is generally overlooked, and consequently causes additional confusion. I refer to the fact that the speaking current in telephony is itself an induced current, and therefore vastly more difficult to confine and control within its own proper circuit, apart altogether from its inductive effect on other wires.

In fact, whilst the induced current has its power to induce another current diminished to one-fourth, its power to use dampness as a medium for completing its circuit by the shortest route is increased a hundredfold as against the power of the primary current to use such a medium. There may be some slight glimmering light in the minds of the telephone management regarding these elementary facts, but how is it exemplified in their work? Let us see.

In leading wires into some of the earlier London Exchanges there appears good evidence of careful design to prevent the effects of induction, because the wires are carefully separated all the way to the switch-boards. On the other hand, the wires leading into the more recent exchanges are tied closely together in bundles, although the insulation on the wires is even less adapted to resist damp. Nothing but some half fledged theory can have originated this bold or reckless deviation from former practice. I can think only of one reason for it, viz., that an induced current may be dispersed through so many closely adjoining circuits as to be inaudible on any. If induction stood alone in the question the change might possibly be a forward step, subject, however, to important qualifications; but, as matters stand, it must inevitably have been a backward step. If telephonists can safely count upon a good long lease of public forbearance well and good, but in the face of the above facts it is too much to expect Parliament to extend their area for such blind experiment.

If the change in the manner of leading wires into the exchanges is to be permanent, then the induction difficulty must be supposed to be at an end, and the objection on that score to putting the wires underground should also cease. But how about the primary question?—effective transmission of speech on its proper line. When the man got his horse to live on one bean a day the horse died.

At the present rate and present style of development, by the time telephonists kill induction their own life as telephonists will be tottering on the brink, for it is no use preventing the speech being heard on other lines if it cannot be heard on its own lines. If resort is to be had immediately to what is termed a complete metallic circuit as the only alternative that must be consequent upon placing the wires underground, then I venture to say the United Telephone Company have no data under their own experience by which to be guided to a successful result. They have had the matter suggested to them to my own knowledge four years ago, and it must have cropped up at sundry times since. They ought, therefore, to be ready before the parliamentary committee to say, if they do not mean to adopt it, why not; and if they do mean to adopt it, how they intend to carry it out.

Otherwise they may use the intention as a means of demanding a higher annual subscription, they may use the fact of a partial adoption of the underground system as the general excuse for faulty working, and soon after abandon it (when it will have served their turn) as unsuitable for such a big city as London.

It may be thought by some who have not to suffer for the absence of care and systematic management in the working of the London telephone system that I am too severe in the above criticism, but if the statements of facts are true, what words, short of criminal charges, would be too severe to use

Digitized by Google

against such stolid disregard of the incessant but well-grounded complaints of the London Telephone Exchange subscribers?

Any of your readers may judge whether I overstated the looseness of system by which the telephonists investigate important technical matters of fact by the National Company's own words in *The Electrician* of March 15.

The company's manager at Dundee had given a testimonial to a certain syndicate, speaking favourably of the conductibility of a new wire conductor. Fearing probably that capital might be subscribed on the strength of that testimonial, the company arranged an exhaustive (?) test by the human ear, using three old wires of the old sorts, and one of the new sort, all the same length.

Incidentally, it seems, the conductivity and insulation of the wires were ascertained by thorough measurement of the various resistances, and the result produced the following figures :—

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| No. 1 conductor : | Resistance | 380 | ohms ; | insulation | 360,000 | ohms per mile. | | |
| 2 | ,, | ,, | 375 | ,, | ,, | 36,000 | ,, | ,, |
| 3 | ,, | ,, | 380 | ,, | ,, | 110,000 | ,, | ,, |
| 4 | ,, | ,, | 251 | ,, | ,, | 92,000 | ,, | ,, |

The above figures seem to have had very little influence on the decision, which was practically contained in the following words :—

"All three observers agreed that No. 1 spoke better than No. 4.

"All agreed that Nos. 2 and 4 were practically alike. Two thought No. 3 was slightly better than No. 4, while the third thought the reverse was the case."

None of the other remarks in their letter could alter the palpable incongruity of the above figures and opinions, and the probability is that the new wire syndicate are using the repudiation of the previous testimonial as the best possible evidence that the first opinion must have been the more correct, for it will be observed that as any electric conductor is wanted chiefly for its conductivity, and as No. 4 has one-third better conductivity and two-thirds better insulation than No. 2, any tests by the ear which pronounce them equally good must inevitably be untrustworthy.

If the company had repudiated the pretensions set forth when this new wire was offered to them, every practical electrician worthy of the name would have given them credit for prompt practical knowledge and judgment, but they had put it on trial on a line four miles long and the trial was agreed to be satisfactory.

It seems it was only when publicity was given to the fact that any doubt crept into their minds, and the exhaustive trial was organised. And with what result? Surely the figures ought to have suggested that they should have consulted some of the scientific witnesses whom they are going to introduce to enlighten the parliamentary committee. But not at all. The idea that their manager's opinion was being used to raise money was too alarming, and the oral witnesses must override even their own figures; therefore scientific experts might be embarrassing.

I have endeavoured to make the foregoing remarks in such a connection as to make them emphatic and impressive. A vast amount of time and money is being wasted for want of attention to the facts stated, and I maintain that under the circumstances no company ought to have the powers asked for. A word to the wise ought to suffice, but to "Telephonist" and other wiseacres I may, perhaps, give a useful hint if they will make the following experiment. When they have the opportunity of listening to what they call induction, let them make a break anywhere in the secondary circuit, and with the hands quite *dry* (or as dry as they can be wiped) take a bare end of the wire in each hand, so that the current has to pass through the body (but if on a long line consider first the possibility of lightning). It will seldom happen that the voices will be much diminished thereby, and ever after there will be great hesitation before calling such stray sounds induction, and some readers will also, perhaps, read again this letter.

I must answer "Telephonist" as to why the policy of the United Telephone Company is contrary to public policy in my next.—Yours, &c.,

MOS LEGEM REGIT.

## A HISTORY OF ELECTRIC TELEGRAPHY TO THE YEAR 1837.

BY J. J. FAHIE, MEMB. SOC. TEL. ENGS. AND ELECS.*

### CHAPTER VII.

(CONTINUED FROM PAGE 526.)

"The inquiry into the laws of dispersion according to which the ground, whose mass is unlimited, is acted upon by the passage of the galvanic current, appeared to be a subject replete with interest. The galvanic excitation cannot be confined to the portions of earth situated between the two ends of the wire; on the contrary, it cannot but extend itself indefinitely, and it therefore only depends on the law that obtains in this excitation of the ground, and the distance of the exciting terminations of the wire, *whether it is necessary or not to have any metallic communication at all for carrying on telegraphic intercourse.*

"An apparatus can, it is true, be constructed in which the inductor, having no other metallic connection with the multiplier than the excitation transmitted through the ground, shall produce galvanic currents in that multiplier sufficient to cause a visible deflection of the bar. This is a hitherto unobserved fact, and may be classed amongst the most extraordinary phenomena that science has revealed to us. It only holds good, however, for small distances; and it must be left to the future to decide whether we shall ever succeed in telegraphing at great distances without any metallic communication at all. My experiments prove that such a thing is possible up to distances of 50 feet. For greater distances we can only conceive it feasible by augmenting the power of the galvanic induction, or by appropriate multipliers constructed for the purpose, or, in conclusion, by increasing the surface of contact presented by the ends of the multipliers. At all events the phenomenon merits our best attention, and its influence will not perhaps be altogether overlooked in the theoretic views we may form with regard to galvanism itself."†

### 1837.—ALEXANDER'S TELEGRAPH.

In May, 1837, William Alexander, of Edinburgh, published a scheme for telegraphic communication, which was the realisation of Ampère's and Ritchie's ideas. It was widely noticed at the time, having appeared in the following amongst other journals:—Edinburgh *Scotsman*, July 1 and November 18; Edinburgh *Evening Courant*, July 3; London *Times*, July 8; and London *Mechanics' Magazine*, August 12 and November 25, 1837. In this paper he showed the practicability of his project, estimated its cost, and pointed out its utility as well to the public as to the State.

After a brief reference to the then existing system of semaphoric signalling, he says :‡—"The plan of a telegraph underground, by means of electric or voltaic currents, transmitted by metallic conductors, was some time ago devised, and its practicability supported by electricians of eminence; but their ideas on the subject have not hitherto been matured, or carried into actual practice upon the scale which is now contemplated."

The following is a description of the apparatus as given by the author at p. 19 of his pamphlet :—

"The model is contained in a mahogany case, or frame, 6 feet long, 2 feet wide, and 3½ feet high.

"The end of the case, intended to face the north, is composed of a wooden board or tablet coloured black with the twenty-six letters of the alphabet, a comma, a semicolon, a full point, and an asterisk, shown on white enamel, at equal distances, in six rows or tiers. The tablet is protected by a sheet of plate glass, and the top or lid of the case is also of glass, for more easy inspection of the interior.

"Behind the tablet are placed (also in six rows or tiers) thirty steel magnets, about two inches long, poised on their centres, so as to admit of their assuming their natural position in the magnetic meridian, and thus having their north poles pointed to the back of the tablet.§ On the north pole of each of the thirty magnets a small piece of brass wire is fixed, protruding through a slit or aperture in the tablet; and from the point of this brass wire a thin piece of brass of about one half inch square, coloured black outside, is suspended.

* The author reserves all rights of translation.

† Sturgeon's *Annals of Electricity*, Vol. III., pp. 450-2. Dr. O'Shaughnessy (afterwards Sir William O'S. Brooke), the organiser of the East Indian telegraphs, claims to have independently discovered the earth circuit, and points for evidence to his paper in the *Journal of the Asiatic Society of Bengal*, for September, 1839, pp. 714-31. See his *Electric Telegraph in British India*, London, 1853, p. 21.

‡ We quote from his *Plan and Description of the Original Electro-Magnetic Telegraph*, &c., 8vo., 30 pp., London, 1851.

§ Many writers, as Moigno and Shaffner, describe and illustrate these needles as suspended *vertically*, which is a mistake.

Digitized by Google

"Each of these thirty pieces of brass, when the needles are in their natural direction of north and south, conceal or veil one of the letters or points marked on the tablet; and in this position the observer of the tablet perceives nothing but one uniform black surface.

"Each of the magnets is poised within a coil of several convolutions of copper wire, and a galvanometer is thus formed.

"At the other, or south end of the model, is a horizontal line of thirty wooden keys, resembling the keys of a pianoforte, and on these keys are marked the twenty-six letters of the alphabet, a comma, a semicolon, a full point, and asterisk, in the same manner as on the tablet. Thirty insulated copper wires traverse the model from the keys to the galvanometers, with both of which they are connected.

"Each galvanometer is also connected by an insulated wire, about three inches in length, with a transverse copper rod, extending from one side of the model to the other. There are six such transverse rods, placed horizontally and at right angles with the six rows or tiers of galvanometers. These copper rods are connected by wires with each other—and a thick copper wire traverses the model from the undermost rod to the south end of the model, and is there connected with the copper plate or positive pole of a small galvanic battery.

"In a small trough or reservoir, extending under the whole length of the line of keys, a small quantity of mercury is deposited, and the zinc plate or negative pole of the galvanic battery is connected by a wire with the mercury in the trough.

"It must be here noticed that the two poles of the galvanic battery are thus connected together by the wires and metallic conductors above described, *except in the space that intervenes between the keys and the trough of mercury placed beneath them.*

"It has therefore, in the next place, to be remarked that thirty pendant platinum wires are attached to the under part of the thirty keys of the model, and that when any key is pressed down with the finger the pendant platinum wire is immersed in the mercury, and the galvanic circuit, by means of metallic conductors, between the two poles (copper and zinc) of the battery completed.

"*The instantaneous effect of the galvanic circuit being so completed is to cause one of the magnets to deflect towards the west, carrying the small brass veil along with it, and thereby exhibiting on the tablet the same letter of the alphabet or point that is marked on the key pressed down.*

"When the finger is taken off the key it rises, by means of a spring underneath, to its former position on a level with the other keys; and the pendant platinum wire ceasing to be dipped in the mercury, the galvanic circuit is again broken, and the magnet returns to its natural position, and veils the letter that was shown on the tablet.

"Hence it follows that by simply pressing down with the finger any of the keys (precisely in the same manner as the keys of a pianoforte are touched), the same letter that is marked on the key is shown on the tablet for a sufficient length of time to allow it to be observed by any person watching the motions of the veils on the tablet, and words are thus communicated in rapid succession from the one terminus of the telegraph to the other.

"When in the course of a communication it is wished to indicate a comma, semicolon, or full period, these will be disclosed on the tablet on the corresponding key being pressed down; and in order to indicate that the spelling of a word is finished, the key marked with the *asterisk* may be pressed down, and the asterisk being at the same instant exhibited on the tablet, will show the observer that the word is completed, and that a new one is about to be spelled.

"In order either to send or receive a communication by a telegraph of the simple construction proposed, no greater learning would be required than is necessary in reading a common book; and the rapidity with which a communication could be made would be as great as that with which most persons are able to write, or as a compositor is able to set up types.

"In telegraphing between distant points, the connecting wires would be made to traverse the intermediate space through a tube of wood, or some other material that would protect the wires from external injury; and the wires would of course be separated from each other by laying them in separate grooves in the tube, or by coating them with some non-conducting substance. The diameter of the tube might be very small, and in order to protect the wires from any atmospheric influence, and the tube itself from violence, it would be best placed under ground.

"Following out the scientific principles that have been explained, and taking advantage of the mechanical contrivances illustrated by the model now exhibited, it appears perfectly practicable to construct an electro-magnetic telegraph surpassing all other kinds of telegraphs in respect to the rapidity, facility, and certainty with which every species of communication can be made between points, however distant."

Having perfected his plans, Alexander submitted them to the Government in the following letter, which he addressed to Lord John Russell, Home Secretary, on June 12, 1837, the date, by the way, of Cooke and Wheatstone's first patent:—

"Edinburgh, 19, Windsor-street,
"12th June, 1837.

"My Lord: I have the honour to enclose for your Lordship's consideration a plan for an electro-magnetic telegraph between Edinburgh and London, and capable of being adopted all over the kingdom with the most important national advantages.

"I have had the honour of submitting the plan to some of the most eminent scientific and influential persons here, and have met with the most flattering approbation from them.

"In order to test the practicability of the plan, experiments have, by the obliging permission of Dr. Hope, the professor of chemistry, been made in his class room in our university, by his very able practical demonstrator Mr. Kemp, both upon a small and pretty extensive scale—a metallic conductor of about four miles in circuit having been operated upon both by mechanical electricity and by galvanism. These experiments have been performed in the presence of Professor Hope himself, and also of the Lord Provost, the Solicitor-General, the Master of the Merchant Company, Sir Charles Gordon (the secretary of the Highland Society), Sir John Hall, Professor Jameson, Professor Traill, Mr. Patrick Robertson, Mr. George Monro, Mr. Hamilton (architect), and other scientific and literary gentlemen, and have proved most satisfactory. A plate of copper and a plate of zinc (about the size of a crown-piece each) immersed in a little acid water were found sufficient to move an ordinary magnetic needle at the termination of a copper wire of four miles in length, notwithstanding numerous oinings and sinuosities in the conducto r.

"Should the telegraph projected ultimately prove capable of the general utility and application contemplated, I humbly think, from its affinity to the Post Office Department, it may prove worthy of the attention of Government, in place of being left to individual enterprise.

"In either case, I venture to hope that sufficient has been already demonstrated both of its practicability and national importance and utility to excuse my bringing the plan under your Lordship's notice, and to request your distinguished patronage.

"It has been suggested to me that the fund, amounting to upwards of £6,000 per annum, administered, subject to the orders of the Lords of the Treasury, by the Trustees for the Encouragement of Arts and Manufactures in Scotland could not be better applied to the extent of a few hundred pounds than by defraying the cost of additional experiments under the superintendence of the gentlemen I have named, or such others as may be selected, upon a still larger scale than it can be expected that individuals should supply for a national object.

"If upon an extent of 50 or 100 miles of metallic conductors the same instantaneous and perfect indication of the passage of the electric or galvanic fluid is found as has been in the case of our recent experiments at the University the triumph of the scheme would be complete.

"May I request the favour of your Lordship's views?

"The Solicitor-General transmitted a print of the plan about a week ago to the Lord Advocate, and I have since made a communication to his Lordship (to whom I have the honour of being known) on the subject.

"I have the honour, &c.,
"W. ALEXANDER."

The reply was as brief and as little satisfactory as those vouchsafed to Wedgwood (1814), Ronalds (1816), Porter (1825), and "Corpusculum" (1832). It ran as follows:—

"Whitehall, 15th June, 1837.

"Sir: I am directed by Lord John Russell to acknowledge the receipt of your letter of the 12th instant, enclosing a plan for an electro-magnetic telegraph.

"I am, Sir,
"Your obedient servant,
"S. M. PHILLIPS."

In December, 1837, Alexander memorialised the Lords of the Treasury on the subject, but with no better fortune.

Alexander opposed the application of Cooke and Wheatstone for a Scotch patent in 1837, but ultimately withdrew his opposition under circumstances which are thus described in a letter of Miss Wheatley (now Lady Cooke), dated December 2, 1837:*—

"I have the pleasure to tell you that the Scotch patent is now free from all opposition, and will be obtained immediately. William

* Extracted by kind permission of Mr. Latimer Clark. See also Cooke's evidence in *The Electric Telegraph Company* versus *Nott and others*, Chancery Proceedings, p. 49. A printed copy of the evidence and affidavits in this celebrated case is preserved in Mr. Latimer Clark's magnificent collection of books on electricity and magnetism—a collection which rivals and, in some respects, excels that of the late Sir Francis Ronalds.

Digitized by Google

had an interview with Mr. Alexander on Thursday at the Lord Advocate's (of Scotland) office, and he agreed to accompany the judge and Lord Lansdowne to see some experiments yesterday at Euston-square Terminus. These proved so satisfactory that Alexander at once acknowledged the superiority of William's and Mr. Wheatstone's plans, and gave up his own. This was an agreeable way of arranging the matter, and William was pleased with Alexander's manner of yielding the point; though, of course, he saw he had no chance of succeeding."

Alexander did not, however, cease to advertise his own invention. Wheatstone, writing to Cooke, December 15, 1837, says:—"Alexander continues to make a great noise about his invention. A few days ago he took it to Kensington Palace for the inspection of the Duke of Sussex; and last night he was at the Royal Society." Early in 1838 he placed it on exhibition at the Royal Gallery of Practical Science, Adelaide-street, Strand;* at the Polytechnic Institution, London, in 1839; at the Glasgow meeting of the British Association, in 1840; and finally at the Great Exhibition (Hyde Park), in 1851.

### 1837—8.—Mungo Ponton's Telegraph.

On the 15th November, 1837, a working model of the apparatus last described was exhibited at the Society of Arts, Edinburgh, and excited the keenest interest amongst all the members present. One of these, the late Mr. Mungo Ponton, was so impressed with the subject that he set about at once to devise a telegraph of his own which should be free from the imperfections with which he saw that Alexander's was hampered; and so rapidly did execution follow upon the heels of design, that in five days, *i.e.*, on the 20th November, 1837, he forwarded to the Society a "Model and Description of an Improved Electric Telegraph." The paper was read at the meeting of the 10th January, 1838, and again, on the 20th June following, a supplement was presented, together with a model of the telegraph in an improved form.†

In the first communication Ponton begins by saying: "When, on a former evening, Mr. Alexander's electric telegraph was exhibited, I took occasion to point out one or two defects under which it appeared to me to labour. These were—1st, the weak and vacillating character of the force employed to discover the letters; 2nd, the great size of the reading board; and 3rd, the very unnecessary multiplication of the lines of wire. Had Mr. Alexander had a just claim to the original invention of an electric telegraph I should have considered it only fair to have pointed out to him the remedies which had occurred to me for the removal of those defects; but as I am led to understand that his claim to originality extends no further than to the mode of constructing the telegraph, I felt myself at liberty to follow out my own ideas.

"The objects I have had in view in the construction of the models now submitted to the Society are—1st, to show how a powerful and decided force may be developed at the reading end of the telegraph; 2nd, how the reading surface may be reduced within very narrow limits; 3rd, how the quantity of motion required for the display of the characters may be made very minute, only a quarter of an inch; 4th, how that motion may be rendered independent of the swing of the needle; and 5th, how with only eight lines of wire we may exhibit all the letters of the alphabet, all the figures, a variety of points and signs, and a considerable number of combinations of letters.

"The first model to which I would call attention is that which shows the method of developing a powerful and steady force at the reading end of the telegraph. This consists of a dipping needle, delicately poised, and furnished with a galvanometer coil. From either side of the centre of the needle is suspended a small slip of wood, from which project downwards the four ends of two bent wires, which dip into mercury cups. The mercury in the cups is connected with the opposite ends of the wires of a pair of common electro-magnets, whose poles are opposed to each other. When one end of the dipping needle is down and the wires on one side touching the mercury in the cup the effect is to make the two electro-magnets attract each other. When the other end of the needle is sent down by means of the electric current passing through the galvanometer coil the effect is to make the two electro-magnets repel each other. In this manner a very considerable and a perfectly steady force is produced, which may be employed for the raising and depressing of levers for the display of the characters.

"Although I should consider this a very decided improvement, yet it is not necessary for the other improvements which I have suggested, and accordingly I have not used it in the construction of the model telegraph now before the society. To that model I would now direct attention.

"It will be seen to contain eight galvanometers, having their needles suspended vertically like a dipping needle. These are placed in two sets of four, piled one above another, each lower needle projecting beyond the one immediately above it. To the end of each needle is attached a fine thread, which is stretched upwards and attached to the bottom of a card. There are eight of these cards placed one before another. They are suspended by threads to the end of eight levers placed one above another. When the needles are in their natural position they hold down the cards against two bars which are placed so as to support them. When the needles are affected by the electric current passing through their coils they swing upwards, and slacken the thread by which the cards are held down, and the cards are then pulled upwards by the levers attached to their upper ends. Their motion, however, is checked after they have moved a quarter of an inch by a piece of wood placed for that purpose. Thus the motion of the cards is rendered in a great measure independent of the swing of the needle.

(TO BE CONTINUED.)

* He also brought it before the Society of Arts, which, however, decided that it was not new, and, on that account unworthy of attention.—Letter, Wheatstone to Cooke, of 24th March, 1838.

† Both these documents are now before us, having been lately discovered after a long search which was kindly made for us by Dr. George Macdonald, of Edinburgh. The model was for many years in the museum of the Society, but on a change of offices it was put away in a damp cellar, where it soon fell to pieces.

## THE SOCIETY OF TELEGRAPH ENGINEERS AND OF ELECTRICIANS.

### INAUGURAL ADDRESS.

Delivered by Professor W. Grylls Adams, F.R.S., 10th Jan., 1884

(concluded from page 570.)

*Testing of Incandescent Lamps.*—The lamps tested were—(1) Edison A 16-candle lamps; (2) Edison B 8-candle lamps; (3) Edison C 8-candle high-resistance lamps; (4) Swan 20-candle lamps; (5) British Lane-Fox high-resistance lamp; (6) Brush Lane-Fox lamp. Six of each of these kinds were tested. Besides these there were also tested—(7) Maxim lamps; (8) Swan small 10-candle lamps; (9) Swan high-resistance lamps; (10) Swan large 100-candle lamps. The efficiency of these lamps was tested, *i.e.*, the ratio of the quantity of light given by each lamp for each unit of electrical energy spent. The electromotive force was measured in two ways—(1) by discharge from the condenser; (2) by a Thomson voltmeter, and roughly by the number of Grove cells employed. The current was measured, (1) by Thomson's current meter; (2) by a tangent galvanometer. The illuminating power of the lamp was measured on a Bunsen photometer, being compared with a lamp of about 17 candles, the accurate value being determined from time to time by careful comparison with a standard candle. The intensities were equalised in each case for red light and for green light (red and green glasses being employed) and the intensity of white being deduced from the mixture of red and green in definite proportions, according to the scale given by Captain Abney.

Through the kindness of Professor Guthrie these experiments were carried out in the Physical Laboratory at South Kensington, by Mr. F. J. Sprague, Captain Abney, and myself, assisted occasionally by Colonel Festing and by Mr. Pierce. The same condenser and Thomson reflecting galvanometer and the same Clark standard cell were used as in the experiments with dynamo machines. The current was obtained from a battery of Grove's cells, and usually each lamp was tested in simple circuit, with battery powers varying from 20 to 50 Grove cells, the small lamps from 10 to 25 Grove cells, the Maxim to 70 cells, and Edison high-resistance lamps were tested to 80 and 85 Grove cells. The object was to determine the law of efficiency of each kind of lamp for different currents, and for illuminating powers far beyond the usual illuminating powers of the lamps. It was thought that this severe test would give also some idea as to the lasting power of the lamp. The resistances of the lamps cold were measured on a Wheatstone bridge, and were as follow:—

| | Edison. B. | Edison. A. | Edison. C. | Swan. | British. | Brush. | Maxim. |
|---|---|---|---|---|---|---|---|
| 1 | 154·2 | 272·8 | 455·7 | 63·0 | 163·3 | 34·3 | 80·2 |
| 2 | 124·8 | 226·1 | 578·5 | 85·0 | 156·8 | 36·3 | 79·9 |
| 3 | 158·5 | 248·1 | 472·4 | 67.0 | 157·7 | 31·4 | 84·1 |
| 4 | 135·7 | 204·1 | 483·6 | 69·8 | 158·7 | 35·1 | 79·9 |
| 5 | 115·0 | 275·1 | 476·6 | 72·4 | 153·8 | 32·6 | 86·0 |
| 6 | 118·6 | 219·7 | 446·7 | 67·6 | 154·5 | 38·2 | 84·2 |

Besides these there were tested—Swan high-resistance lamps Nos. 13 and 14; Swan low-resistance 8-candle lamps, Nos. 15 and 16; Swan large 100-candle lamps, Nos. 17 and 18.

| No. and Resistance. | | | | | |
|---|---|---|---|---|---|
| 13 | 14 | 15 | 16 | 17 | 18 |
| 194·0 ... | 186·2 ... | 26·4 ... | 20·0 ... | 47·8 ... | 53·8 |

An elaborate series of experiments was carried out by Mr. Sprague and myself to determine the constants of the current-meter and the voltmeter. The constant of the current-meter was found by comparison with a tangent galvanometer whose constant was carefully determined, and the value was less than the value given with the instrument, in the ratio of 15 to 16. The value of the constant for the current-meter was ·150—*i.e.*, the reading of the instrument when multiplied by this number gave the current in amperes. The value of the constant of the voltmeter was $\frac{7·1 + ·18}{2} = \frac{7·28}{2} = 3·64$. The different graduations of the platform of the voltmeter were found to be consistent with one another.

Digitized by Google

The calculated results are given in the following tables :—

As an illustration of the method of working out the characteristic curves for incandescent lamps, take the Edison B lamp No. 4.

Resistance (cold) = 135·7 ohms.

For measurement of *Current*—

$$\text{Constant of current-meter} = \frac{6{\cdot}54}{43{\cdot}6} = {\cdot}150 = \frac{3}{20}.$$

| Cells..... | 20 | 25 | 30 | 35 | 40 | 45 | 50 |
|---|---|---|---|---|---|---|---|
| Readings | 2·9 | 4·0 | 4·8 | 5·95 | 6·9 | 7·95 | 8·7 |
| Currents. | ·435 | ·6001 | ·7199 | ·8925 | 1·035 | 1·192 | 1·305 |

For difference of potential at the poles of the lamp—

(1) By Thomson's voltmeter.

$$\text{Constant} = \frac{7{\cdot}1 + {\cdot}18}{2} = 3{\cdot}64 \text{ (log. } 3{\cdot}64 = 0{\cdot}5611).$$

| Readings. | 10 | 12·4 | 14·7 | 17·0 | 19·1 | 21·3 | 23·5 |

| Volts ..... | 35·49 | 43·31 | 51·33 | 58·94 | 66·97 | 74·63 | 81·91 | 96·10 | 102·3 | 109·3 |

From the value of $\frac{E}{C}$ for Maxim lamps it appears that up to a little beyond 300 candle-power the resistance continues to diminish, but that the resistance for higher illuminations again increases, showing that from about 300 candle-power the breaking down of the lamp has begun, and the lamps break after attaining an illuminating power of about 450 candles.

The characteristic curve for Maxim lamps is not continued to the extreme value in Fig. 7, but is of the same general character up to the

Digitized by Google

point where it begins to break down. At 32 candle-power there is a yield of 240 candles per horse-power as compared with 342 candles for Edison lamps and 415 candles for Swan lamps. At 40 candle-power there is a yield of 280 candles per horse-power as compared with 400 candles for

Edison lamps and 500 candles for Swan lamps. At 140 candle-power the yield is 600 candles per horse-power, *i.e.*, the economical efficiency is the same as the economical efficiency of Swan high-resistance lamps at 60 candle-power for each lamp. The efficiency of the Maxim lamp becomes about 920 candles per horse-power when the lamp is giving an illumination of about 300 candle-power, and so is comparable with the efficiency obtained in lighting by the electric arc.

With the Maxim lamp the illumination was not equal in all directions, on account of the flatness of the filament. At half a right angle from its position of brightest illumination the candle-power was reduced about 7 per cent., and near the plane of the filament the illumination was only about 75 per cent. of the brightest illumination.

## THE INDO-EUROPEAN TELEGRAPH COMPANY (LIMITED).

The seventeenth ordinary general meeting of the members of this Company took place on Monday at the City Terminus Hotel, Cannon-street, under the presidency of Colonel James Holland.

The MANAGING DIRECTOR (Mr. W. Andrews) read the advertisement convening the meeting, the common seal of the Company was affixed to the register of shareholders, and the report of the directors was taken as read.

The CHAIRMAN: The leading feature of the accounts for the past year I may say is one which the directors in the interest of the shareholders always like—it has been a quiet year; it has not been marked by any extraordinary event, but our usual course of events has followed on unchecked and in a very prosperous and pleasant fashion. We have not made anything like the amount of profit we made last year, but as you will remember that year was altogether exceptional. The wires of the submarine cables being destroyed or in possession of the enemy, we had for some months the whole business of conveying telegraphic intelligence between Europe and the East thrown upon us, and if you will carry your memory back a year or so you will remember that we did that work without any increase of cost, and I may say in a very efficient manner. The sum total of our receipts for 1883, in round figures, was £100,000, against £118,000 in the preceding year, and the difference of £18,000 marks the extra sum which we received for the extraordinary work which we did. This £100,000 can hardly be said to represent a very flourishing state of business, because trade has been very bad, and continues very bad; and until there is an improvement in the general trade of the country we cannot expect the business of this Company—any more than that of any other Company—to be materially increased. The expenditure, however, is a matter over which we have more control than we have over the receipts, and it may be interesting to you if I read the sum total of the expenditure in the last four years. In 1880 it was £56,632, in 1881 it was £57,875, in 1882 (the exceptional year, when there was a slight addition) it was £58,648, and last year—the year we are now dealing with—it was £54,754. These expenses would remain practically the same if the Company's work was doubled, as was shown last year on the total interruption of the Eastern Company, because staff and other arrangements have to be kept up to the maximum of efficiency to provide for the emergency of dealing with the total trade exchanged with India and the East if necessary. The items composing that £54,000 odd I have in my possession, and if any gentlemen wishes to go into them I shall be happy to do so. If not I presume they will be satisfied with what I have said as to the total showing a diminution in the expenditure of £4,000, and certainly with no decrease of efficiency. We propose a dividend virtually of 8 per cent. Last year, as you know, it was 9 per cent., but last year, as I have said, was an exceptional year, and I think the shareholders have some reason to be satisfied with 8 per cent., and I hope they will be. Another matter for congratulation is that the long-looked for termination of the absorption of our funds by the so-called Persian debt has arrived with this report. We have paid the last amount, and henceforward for the next eleven years we shall be receiving back the amount we have paid in sums of a little under £2,000 a year. That will add so much to our resources. This is a matter distinctly for congratulation, because though we knew this was coming, yet somehow or another I think shareholders generally prefer the funds actually in their possession without having to say they expect them. There is nearly £22,000 to come to us in that way in the next eleven years. We note also in our report that the Company has opened a branch office in Mincing-lane, and has leased from the Post Office a special wire. These measures are part of the measures which are constantly engaging our attention, our object being to make the business of the Company more "comeatable" at all times, to improve our efficiency, and place the means of communication in the hands of the merchants in all parts of London as complete as we can. It is on the efficiency of our working that our success must depend. We have also to notice with satisfaction the conclusion arrived at at the Cable Conference I spoke of at our last annual meeting, a conference assembled for the protection of submarine cables. That conference has terminated its labours, and regulations have been passed which will, to a very great extent, reduce the chance of injury to our submarine cables for the future. I have now to refer to a painful matter—one of those incidents which in the age of companies as in the age of man are constantly occurring—the loss of a valued constituent and friend, the loss of Sir William Siemens, who died prematurely. He was, as you know, a man of great European reputation, and his loss may be said to be of a national character, for few men combined, as Sir William Siemens did, the greatest scientific skill with the power of applying that skill. I have also to mention another loss—not so deeply felt as that of Sir William Siemens, but a loss very much felt by those sitting on this side of the table, and I am sure by the shareholders also. I refer to the death of our first chairman, the Hon. Robert Grimston, who died a few weeks ago. Mr. Grimston was a man who held the reins of office in this Company during the hard times that preceded what I may call the dividend period. He had to go through the whole of the hard work and labour—the unremunerative part. It was a very painful office he had to fill very often in coming before the shareholders. The feeling he has left behind on the part of his colleagues is one of warm affection. We felt that he was not only a man of ability and energy, but of that kind and genial nature which attached all of us to him; and I am sure you will join us in our expression of regret. I have nothing further to add beyond proposing, "That the report and statement of accounts be received and adopted."

Mr. H. WEAVER seconded the motion.

The CHAIRMAN then expressed his willingness to answer any questions, but no gentleman rising to address the meeting, he put the motion in the usual way, and it was carried unanimously. Continuing he moved the following resolution:—"That a dividend be and is hereby declared for the half year ended December 31 of 17s. 6d. per share—making, with the interim dividend already paid, 6 per cent. for the year—and a bonus of 10s. per share, both free of income tax, making in all 8 per cent. for the year.

Mr. J. HERBERT TRITTON seconded the motion, which was carried unanimously.

The CHAIRMAN next moved the re-election of Mr. Weaver and Mr. Delbrück, observing that the latter gentleman was one of their foreign corresponding members, and a gentleman of influence in his own country. As to Mr. Weaver, it was quite sufficient merely to mention his name in any assembly of London business men.

Major-General G. B. TREMENHEERE, R.E., seconded the motion, which was carried unanimously.

Mr. WEAVER having returned thanks on behalf of Mr. Delbrück and himself,

The CHAIRMAN stated that Messrs. Kemp, Ford, and Co., retired from their position of auditors, and the question of their re-election was one for the shareholders' decision. He first of all, however, wished to read a letter received by Mr. Andrews from Messrs. Kemp, Ford, and Co. The letter, which he proceeded to read, referred to the fact that, notwithstanding the large increase in the business of the Company, the audit fee had remained unaltered at 50 guineas per annum from the commencement, "and, further, since the termination of your contract with Messrs. Siemens, we have had to check the maintenance accounts, which are very voluminous, and have entailed a large amount of additional work." They therefore submitted that the audit fee for last year, and in future years, should be 100 guineas. On receiving this letter the directors had thought it their duty to make inquiries, and they found that what Messrs. Kemp and Co. stated was fully borne out—that owing to the Company having taken over the maintenance themselves (an arrangement which was working very satisfac-

Digitized by Google

torily) the labours of the auditors had been very materially increased, and that their past audit occupied them between three weeks and a month with the whole staff of their company. Under these circumstances the directors did not think it at all an unreasonable request that Messrs. Kemp and Co. had made.

On the motion of Mr. MATTHEWS, seconded by Mr. WOODMAN, Messrs. Kemp, Ford, and Co. were re-elected, at a remuneration of 100 guineas per annum, to take effect from January 1, 1883.

A vote of thanks to the chairman and directors was next passed, and

The CHAIRMAN having acknowledged the compliment, the meeting separated.

## THE ORIENTAL TELEPHONE COMPANY (LIMITED).

The ordinary annual general meeting of the shareholders of this Company was held at the City Terminus Hotel, Cannon-street, on Wednesday, the 30th of April, 1884, under the presidency of Mr. John Pender, M.P.

The SECRETARY (Mr. W. G. Hall) read the notice calling the meeting, and also the minutes of the previous meeting, which were duly confirmed, and signed by the chairman.

The Directors' report and balance-sheet were taken as read.

The CHAIRMAN, in moving their adoption, said that although he could not put before the shareholders a very brilliant state of affairs, still he could say with some confidence that the Company's position was by no means an unsatisfactory one. The Company had been not much longer than two years in existence, and those who attended its first meetings, at which he presided, would remember that he drew attention to the fact that he believed the telephone was to some extent an assistance to telegraphy, and it was for that reason, as he stated, that he had gone out of his usual way to take an interest in this telephone system. So far as he could see now, the telephone in such countries as Egypt, India, and China, and wherever they had established it, was used to a greater or less extent for mercantile purposes, and was therefore a great aid to telegraphy, and as it was developed it would become increasingly so. He found in India with respect to the use of the telephone pretty much the same prejudice as he found with respect to the use of the telegraph in its earlier days. The people of the east did not move so quickly as those in the western world, and consequently the development of the Company's business had been slower than that of similar companies in Europe and America; but the growth of telephony even in England, where it might be supposed its advantanges would be very much appreciated, had not been as rapid as some believers in it imagined it would be. The Company had got systems established in Alexandria, Cairo, Suez, Calcutta, Madras, Bombay, Kurrachee, Rangoon, Colombo, Singapore, Hong Kong, Shanghai, and Port Louis, Mauritius. As to Alexandria he believed that, had it not been for the unfavourable state of affairs that existed there since the Company was organised, that town would have been of itself able to return sufficient to pay interest upon the capital they had invested. Even in the present state of things it was remarkable how much the telephone was used both at Alexandria and Cairo, and he had no doubt that as trade returned its development would rapidly advance, and that the returns would be correspondingly satisfactory. In respect to Calcutta and Bombay, there could be no question that those towns would before long come under what he would call the influence of the telephone. Its advantages were so great that it was next to impossible that it should not be largely adopted by the mercantile European element of the population. They were beginning to get a footing in China, too, where, the moment the natives realised the advantages of the telephone, he looked for a very rapid extension of the Company's business. The same might be said with respect to Bombay. Madras had always been a slow place, but even there there was some evidence of life in the same direction. And he might say generally that, with the exception of China, there was no place where the Company's system had been established which did not show some progress, though it was slow. The Company had a good property, and all that it wanted was careful watching and economical management to make it a profitable source of investment to the shareholders. Their interest in the Hawaiian system the directors had found it expedient to dispose of, inasmuch as they could not exercise that control over it which it was desirable in the interests of the Company they should do. He might mention that Mr. Carnegy, one of their directors, had recently returned from India, where he saw the Company's system at work, and that gentleman entirely confirmed the opinion which he had ventured to give in respect to Bombay and Calcutta. What he particularly desired to impress upon the shareholders was that this being a new business they ought not to be in too great a hurry to receive large dividends. The shareholders would see that their accounts, by the advice of their accountants, had been dealt with pretty much in the same way which other telephone companies dealt with theirs. They were aware that large sums had been paid for patent rights, and when those patent rights were sold to different sections, a part of the money acquired by the sale was paid in dividends, a course adopted under the advice of the auditors. It was a matter for the shareholders to decide, whether they would prefer to leave the money in the coffers of the Company or to use it in that method. His own opinion was that the accountants' advice was sound, and believing that this was probably the most critical year that the Company would have to pass through in regard to returns, it would have been a most unwise thing not to avail to a small extent of the profit which accrued from the sale of their patent rights, as the directors proposed, in the form of dividend. The meeting would observe by the report that he retired from the Board. The circumstance arose in this way. When he joined this Company he stated that for a couple of years (believing that he could be of some assistance in establishing the Company in India, Singapore, and other places with which he was more or less connected) he would be most happy to serve the Company. Now that had been accomplished, and, as he had stated, the Company required a great deal of personal attention. It was more the details of the business than a broad policy that had to be attended to at the present time. He was happy to say there were gentlemen on the Board thoroughly conversant with telephonic matters. He referred more particularly to Colonel Gourand, who had been connected with the telephone from the first, and there was probably no man in this or any other country who knew more about it than that gentleman. He might also say that the Company had a secretary who had devoted his time and thought to it in a degree which the directors fully appreciated, and no one more than he did. He would be perfectly contented to leave the management of the concern in the hands of these two gentlemen. At the same time, let them not imagine that he wanted to leave the Company without still giving it what assistance lay in his power. He desired to reduce as far as possible the amount paid to the Board, and in the ordinary course of events the ballot had to be taken as to who should retire therefrom. It so happened that he himself, his son, and Sir Alexander Armstrong were balloted out, and therefore, believing in practising what he preached, he declined to be re-elected. At the same time, he would be quite willing to act with any prominent shareholders as a sort of consultative committee, to give the directors advice and the benefit of any experience they possessed without charging the Company a shilling. He suggested that a consultative committee should be formed consisting of Mr. B. St. John Ackers (whom he described as the largest shareholder), himself, and some other leading shareholder. This suggestion seemed to meet with a very general approval from the shareholders present. He concluded by formally moving "That the accounts made up to the 31st December, 1883, and showing the transfer of the sum of £10,000 to profit and loss account from suspense profit account on conversion of the Egyptian Exchanges, together with the directors' report now submitted to the meeting, be approved and adopted, and that the dividend recommended by the directors for the year ending 31st December, 1883, of 5 per cent. per annum, free of income-tax, be and is hereby declared on the ordinary shares of the Company other than the vendors' shares."

The DEPUTY-CHAIRMAN (Colonel G. E. Gourand) seconded the motion, expressing his belief in the wisdom of the course adopted by the Board as to the payment of the dividend, and personal regret at the retirement of Mr. Pender from the directorate. It was in consequence of that regret that he had suggested that there should be a small consultative committee to advise with the Board on which Mr. Pender might be pleased to act, so that the Company would not lose the benefit of his experience and counsel.

The CHAIRMAN, in reply to Mr. Wainwright, said that there was a marked progress in Egypt in telephony. In Alexandria and Cairo the increase in the number of subscribers to the Exchange and private lines during the year had been 187, and the gross income now amounted to £6,600, with the prospect of that amount being doubled so soon as some form of government was established there. So long as England was supposed to but did not rule Egypt they could not expect either commerce or agriculture to prosper or progress. The prospects all round were good. He concluded by referring to the excellent way the books were audited.

The motion was then put and carried unanimously.

The CHAIRMAN afterwards read a letter from Mr. Ackers, the substance of which was to the effect that he would be willing to act with the chairman as a consultative committee, and Mr. Pender expressed his readiness to fall in with the proposal.

The re-election of Sir Alexander Armstrong, K.C.B., &c., not being proposed nor seconded, he retires from the Board.

Messrs. Deloitte, Dever, Griffiths, and Co. were reappointed auditors, and a vote of thanks having been accorded to Mr. Pender for his past services to the Company and his conduct in the chair, the proceedings terminated.

## THE PROVINCIAL (BRUSH) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Tuesday, at the Cannon-street Hotel, Sir Michael Kennedy in the chair.

Mr. ALFRED JERMYN (the secretary) having read the notice convening the meeting,

The CHAIRMAN said the directors had called this meeting in answer to what they believed to be a very general desire to reduce the capital of the Company, and thereby to still further limit the liability upon the shares, and the resolution which they would have to consider provided for doing that to the greatest extent practicable, having regard to the engagements and liabilities of the Company, which in any case would have to be met. They must not disguise from themselves that by adopting this measure they must submit to some present sacrifices which would curtail their opportunities of dealing with any business that might be offered to them, and it would entail the entire loss of their provisional orders, which had been obtained with some little trouble and at considerable expense. The prospects of electric lighting at the present moment, he was sorry to say, were not so bright as they all expected and hoped they would be at one time, but he felt confident that a turn would take place before very long in this respect, and he hoped the measure they were about to adopt would not prevent them from taking advantage of that turn when it did take place. Recently they made a very similar arrangement in the South Eastern, and the committee of shareholders who acted with the Board in that matter expressed the opinion that the measure of reduction would not hamper them in raising further capital should they require to do so at any future

Digitized by Google

time. Their policy, then, was to lie by for a time, and in the meanwhile to reduce their outgoings to the lowest practical limit. In this view they had made arrangements for carrying out large reductions both of establishment and salaries; they proposed to move into cheaper offices, and the directors, until a dividend had been earned, would not take any further remuneration. The ultimate result of all these reductions would be that their working expenses would be brought down to about £700 per annum. There was a slight mistake in the resolution as circulated, inasmuch as the capital there had been assumed to be £100,000 in £20 shares, the fact having been overlooked that the capital was £99,205 and the shares 19,841, so that they had to make a corresponding verbal alteration in the motion which he would have to submit. The resolution, therefore, he had to move was as follows:—"That the capital of the Company be reduced from £99,205 to £54,562 15s., and that such reduction be effected by reducing by £2 5s. per share the liability upon each of the 19,841 shares of £5 each now in issue."

Mr. FRY, in seconding the motion, said that the shareholders must not expect the directors to do in future more than the limited amount of capital at their disposal would allow them to perform. All he could say was that the Board would do their best to bring the Company to a success.

The motion was then put, and carried unanimously.

A SHAREHOLDER asked if it was the intention of the Board to call up the remaining 5s.

The CHAIRMAN replied, not immediately but eventually they would have to call it up.

Another SHAREHOLDER suggested that the 5s. would be for liquidation purposes.

The CHAIRMAN said he would be happy to answer any questions, but as the motion had been put and carried a discussion would be irregular.

A SHAREHOLDER asked what capital there was in hand.

The CHAIRMAN answered £3,577, and there was an unpaid call of £790, from which they expected to realise £250.

A SHAREHOLDER thought it was rather a pity that the promising appearances he had heard of at the office were not noticed. He was told that Colchester was to be lighted up almost immediately by their system, and it was a great pity if there was such encouragement and expectation before them that there should be any talk of liquidation. He thought the directors should be supported in every way.

The CHAIRMAN said that he did not refer to Colchester because it was not this Company that had to do the work, but no doubt the shareholders of this Company had an interest, if not a direct interest, in the success of the work. The managing director could tell the meeting what had occurred, and also give an account of the progress of the Consolidated Company and its manufacturing operations, upon which the success of this Company also greatly depended.

Mr. OFFOR: Mr. chairman and gentlemen, it is satisfactory to be able to mention to the shareholders that the B.T.K. system, which we have adopted, of house to house supply of electric light by means of storage batteries has already been carried out during the last week, after long delays in getting the apparatus made and fixed and so on, but it has been carried out, as the shareholder remarked, at Halton House, the residence of Mr. Alfred Rothschild. The installation there is practically the same as that which is being carried out for house to house lighting at Colchester. We have the same system of storage batteries, the same method of governing the current by means of a master cell and rocking switches, all of which apparatus you will have the means of seeing at the Health Exhibition, where we intend to exhibit on the opening day; consequently we have the satisfaction of knowing that our system is a practical one and will work, because the result of the experiment at Mr. Rothschild's is so thoroughly satisfactory that we have not the slightest doubt that the more extended operations at Colchester will be equally successful. Now, our test at Colchester is simply this:—To-morrow week the trial lighting will be made; we have had considerable delay in connection with Colchester, but I am quite sure that all who are practically acquainted with this subject will very readily understand that in carrying out an entirely new system, that has never been adopted before in any part of the world, almost as a matter of course they have had to meet with delays. Those who are practically acquainted with this subject will know that however well you may design your system you have to get machinery made to manufacture the apparatus, and when you have your machinery made you have to prove it, and so delays take place. Many little things crop up when you are practically applying the system which you have not anticipated; they have to be met and provided for. Now this accounts for what appears a long delay to you, but probably in the history of this new enterprise it will be looked back upon as a very short delay. If we have really accomplished in some eighteen months a system for the supply of electricity on the same lines as the gas supply, namely, simply putting a wire into a man's house, and from that wire he shall receive a constant supply of electricity without being entirely dependent on the working of machinery—I say if we have accomplished that in eighteen months, and in accordance with the very harsh rules laid down by the Board of Trade, I think you will admit, with all our impatience and desire to get the thing done quickly, we have accomplished in this short time a very great work. Now, the installation at Colchester, I may mention, consists of the supply of electricity from a central station, conveyed to storage stations in different parts of the district to be supplied, not in every one's house, but in stations which supply a group of houses. From these stations the houses are supplied. We charge our batteries by means of the excellent Brush high tension machine, we charge the whole of our batteries in series at one operation, and we deliver from those batteries by means of our rocking switch arrangement the low tension current, and at no period during the charging of the batteries is a high tension current in communication with the houses. Now, that is the special feature in connection with the system which we are working, and that has been proved to be a success at Mr. Alfred Rothschild's, and therefore we have no reason whatever to doubt that that which has succeeded at Aylesbury will be equally successful at Colchester. The trial at Colchester having to be made within a very few days before you meet here again to confirm the resolution which you have just passed, you will no doubt have had the whole history of our Colchester business published. With regard to the prospects in the immediate future, I may be accused, perhaps, of being a very sanguine man, but from what I see from communications I have with those who are connected with this industry I have not the slightest hesitation in saying that the only difficulty we shall have after our Colchester installation is known to the public will be to produce the apparatus and to find men to fix it. As to the demand, there is not a question about it. As you are probably aware, provisional orders were not only granted to companies like ours, but a large number of these orders were granted to local authorities. Now, these local authorities do not suffer from the question of capital, which the private companies are likely to suffer from. You have become impatient, and naturally so, at the want of a result within the time that this Company has been formed, and in consequence you are desirous, from a loss of confidence, no doubt, in the whole industry, of reducing your liabilities. In the act that you have just perpetrated, if I may be allowed the term, you to a certain extent injure the industry, because the public generally, who are not shareholders in electric lighting companies, form their opinion of the practicability of electric lighting from the action of the shareholders. They say there is nothing in it, because the shareholders are clamouring to wind up or reduce their liabilities. That feeling is no doubt injurious to us. But just to recall you to the action of the local authorities who have obtained provisional orders, we are in communication with those local authorities, and in some cases they are only waiting the result at Colchester before entering into serious business arrangements with us. I have had within the last fortnight a sub-committee from one of the local authorities in question who have been anxious about this Colchester matter, because it has interfered with their making the necessary arrangements for carrying out their order, and they will proceed immediately our installation is going. I take only this one local authority, and that not of the largest kind—not like Leeds, Bradford, or others, where they have taken provisional orders, and the business in carrying those orders out will be simply gigantic—but I will take this one, the sub-committee of the local board having been with me within a few days. They say "We are on bad terms with our gas company; we have a bad supply of gas at a high price. Therefore, we have obtained provisional orders, and have made arrangements for the borrowing of £40,000 for the works necessary for carrying out Schedule A." That is the compulsory area which they are bound to supply electricity in within two years of the date of their order, which was granted last summer. Now, the total requirement of that Board will be 60,000 lamps, and you can appreciate what amount of plant will be necessary to supply those. The same negotiations are going on with us from other local authorities. We have carried out a most important installation on the B.T.K. system, which is working successfully. Next week you will have the first attempt throughout the world of house to house lighting by this system, which is as nearly as we can make a system on the same lines as the gas supply.

A vote of thanks to the chairman and directors then terminated the proceedings.

## THE BRUSH ELECTRIC LIGHT AND POWER COMPANY OF SCOTLAND, IN LIQUIDATION.

A meeting of this Company was held at the offices, Dashwood House, Old Broad-street, on Tuesday, but as the representatives of the press were refused admission we are unable to furnish our readers with any details of the proceedings.

## SUBMARINE CABLES TRUST.

Report of the trustees to the thirteenth ordinary annual meeting of the certificate holders, to be held at the offices of the Trust, No. 66, Old Broad-street, London, on the 13th inst.: The revenue for the twelve-months, including the balance brought from last year's accounts, viz., £2,185 19s. 4d., amounted to £26,176 3s. The dividend and bonus on the Eastern Extension Company's shares (£3,651 9s.) and the dividend on the Eastern Company's shares (£1,350 12s. 6d.) in respect of profits to 31st December last, although not paid until after April 15th, were declared prior to that date, and are, therefore, as usual, included in the revenue for the past financial year. The trustees in May last purchased in the market seven certificates at a cost of £777, thus reducing the number of outstanding certificates to 3,390. To effect this operation it was necessary to withdraw from the past year's revenue the sum of £569 11s. 3d., the balance of £207 8s. 9d. already standing to the credit of the "Redemption Fund." The expenses of the Trust for the twelve months amounted to £1,323 2s. 4d. The payment of two half-yearly coupons at the rate of 6 per cent. per annum absorbed the sum of £20,340, leaving a balance of £3,943 9s. 5d. to be carried forward. The securities held by the trustees since the issue of the last report remain unchanged. The usual table showing the original and present investments of the Trust is appended to this report. The meeting will have to elect two auditors for the current year; Mr. John G. Griffiths and Mr. John Gane, the present auditors, offer themselves for re-election.

Messrs. CROMPTON & CO. are prepared to give Estimates, and to undertake the complete installation of the ELECTRIC LIGHT, either with the Arc or Incandescent system.

Digitized by Google

## NOTES.

TELEGRAMS FOR MARANHAM AND PARA.—The cable between Maranham and Fortaleza is repaired.

MONTREAL.—The electric light is now used in four churches in Montreal.

THE GRAMME MACHINE.—On the 8th prox. the British patent for the Gramme machine expires.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic receipts of this company for April amounted to £21,040.

TELEGRAPH APPOINTMENT.—Mr. J. Jordan, sorting clerk and telegraphist at Preston, has been appointed postmaster at Newton-le-Willows.

TELPHERAGE.—Professor Fleeming Jenkin, F.R.S., will give a paper on this subject at the meeting of the Society of Arts on Wednesday next.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this company for the week ended 25th ult. amounted to £3,300.

DIRECT SPANISH TELEGRAPH COMPANY.—The estimated traffic receipts for the month of April, 1884, are £1,800, against £1,778 in the corresponding period of last year.

EASTERN TELEGRAPH COMPANY.—The Eastern Telegraph Company's traffic receipts for the month of April, 1884, amounted to £51,974, and to £45,148 in the corresponding period of 1883.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of April amounted to £31,246, and to £32,005 for the corresponding period of 1883.

NICARAGUA.—The Post Office notify that the Nicaraguan Telegraph Administration is now prepared to investigate complaints respecting irregularities in the transmission or delivery of telegrams, which hitherto it has declined to do.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts for the week ending May 2, 1884, were £2,990, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company.

INCANDESCENCE LIGHTING.—The North German Lloyd's steamship "Ems" has been fitted with 320 incandescence lamps and a masthead arc lamp, under the direction of Mr. J. D. R. Andrews, of the Woodside Electric Works, Glasgow.

LECTURE.—We understand that Mr. A. Reckenzaun, C.E., will give a lecture on "Electricity, its Application to Public Works and Buildings, Motive Power, &c.," at St. James's Hall, Regent-street, to the Clerk of Works Association, on Thursday next.

PROFESSOR FRANKLAND.—The *Science Monthly* for the present month contains a notice of the life and labours of Professor E. Frankland, D.C.L., F.R.S., in which it is mentioned that he is the discoverer of new methods of constructing electrical storage batteries.

IN RE J. B. ROGERS'S ELECTRIC LIGHT AND POWER COMPANY.—The Vice-Chancellor made an order for compulsory winding up on the petition of Messrs. W. T. Glover and Co., creditors of the company. The company's property was in the possession of a receiver.

HULL.—The oil mill of Mr. Gray has been lighted by means of 50 incandescent lamps. The work has been carried out by the Anglo-American Brush Company, and under the supervision of Mr. Geipel. In this installation a Victoria compound wound $B_2$ dynamo is used.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the general monthly meeting, held on the 5th inst., Mr. Warren De La Rue, M.A., D.C.L., F.R.S., manager, in the chair, Messrs. Rookes Evelyn Crompton, Ernest George Mocatta, Ernest Robert Moon, and John Lawrence Tatham were elected members of the institution.

CUBA SUBMARINE TELEGRAPH COMPANY.—The number of messages passing over the lines of this company during the month of April was 3,801, estimated to produce £3,300, against 4,413 messages, producing £3,982 in the corresponding month of last year. The traffic receipts for the month of January, estimated at £3,000, realised £3,009.

THE EXHIBITION AT PHILADELPHIA.—Jerome Carty, of Philadelphia, who during his sojourn abroad has consented to represent the International Electrical Exhibition to be held at Philadelphia in 1884, is staying at the First Avenue Hotel, Holborn. He requests us to state that he will be pleased to furnish any information desired to those interested in this exhibition.

ELECTRICAL EXHIBITION AT BRUSSELS.—The Town Council of Brussels have resolved to hold an exhibition of apparatus for lighting by gas and electricity at Brussels in 1887. It was at first proposed to hold it this year, but the consideration that Antwerp is to be the scene of an exhibition this year, at which electricity will be prominent, caused the Brussels project to be postponed.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY.—The general meeting of the shareholders of this company will be held at the offices of the company, 66, Old Broad-street, on Thursday, 22nd May, at 12 noon, to receive the directors' report, and to declare a dividend. The register of transfers will remain closed from the 15th to the 22nd May, both days inclusive.

THE ELECTRIC LIGHT IN THE HOUSE OF LORDS.—Replying to Earl Milltown on Tuesday last, Lord Sudeley stated that the whole question of lighting up the Houses of Parliament with electric light was at present under the consideration of the First Commissioner of Works. Plans and estimates were being prepared with respect to the lighting up, not only of the library, the corridors, and galleries of that House, as was now done in the House of Commons, but also the actual chamber of their lordships.

TENDERS FOR ELECTRIC LIGHTING.—The Managers of the Metropolitan Asylums Board invite plans, specifications, and estimates for lighting, and the annual expense of keeping lighted, by electricity, the three hospital ships and stations on shore at Long Reach, near Gravesend. The machinery must be on the shore, or at least so placed as not to disturb the patients or officers. Tenders are to be delivered at the offices of the Managers, 37, Norfolk-street, Strand, W.C., by the 23rd May next. All further information may be obtained of the clerk to the Managers, Mr. W. F. Jebb.

CEYLON-INDIA CABLE.—The cable between Ceylon and India, says *Colonies and India*, which has so often got out of order, and was only a few months ago the subject of a deputation to the Governor, has again got damaged, and messages are at present being conveyed across the Paumben Channel by the Colombo harbour tug, "Active," the Indian Government having telegraphed to the Colombo Postmaster-General asking

Digitized by Google

for her services to aid in picking up the damaged cable. It is fortunate that the sea was calm in the Paumben Channel, otherwise much delay and trouble would be experienced in the repairing.

OH! FOR THE ELECTRIC LIGHT!—The following letter appeared in the *Pall Mall Gazette* on 6th inst., signed "St. John's Wood:"—"Sir: Can any one explain the reason for the sudden increase of all our gas bills? My own, which came in the other day, is nearly 30 per cent. in excess of that for the corresponding quarter last year. As we have not been burning more gas than usual I sent the meter to be tested, but it appears to be all right, and I now find that a number of my friends are in the same case. The gas is certainly very bad in quality. Is it possible that bad gas is consumed more quickly than good? If so, there should be a reduction in the price."

THE RECENT INTERRUPTION OF TELEGRAPHIC COMMUNICATION AT GLASGOW.—The Glasgow magistrates having complained to the Postmaster-General of the recent interruption of telegraphic communication, have been informed "that the question of interruptions of telegraphic communication has been frequently under consideration; that these have not occurred in any particular locality, but in various parts of the country; that the placing of one section of the lines under ground would not, therefore, ensure immunity from interruption, while the cost of substituting underground wires throughout the kingdom, or even between the principal towns, precludes its adoption."

THE ELECTRICAL CONFERENCE AT PARIS.—The International Electrical Conference at Paris, participated in by European and Asiatic States, completed its labours on Saturday last. The subjects of deliberation were arranged under three heads:—Electrical Unities proper, Electric Currents and Lightning Conductors, and, finally, Standard of Light. M. Cochery, the Minister of Posts and Telegraphs, in taking leave of the members, said the work on which they had been engaged would provide the means of extending and developing electrical industry, and expressed the assurance that their labours just concluded would be ever memorable in the annals of electrical science. We give the resolutions adopted at this conference in another column.

CORPS OF VOLUNTEER TELEGRAPH CLERKS FOR ARMY SERVICE.—Colonel du Plat Taylor having now obtained the sanction of the Secretary of State for War and Postmaster-General for the formation from the members of the Post Office Volunteers of a corps of fifty telegraph clerks for service with the Army, has received applications from more than double that number of volunteers, and steps will at once be taken for organising this corps. These men will enlist for six years, and be placed in the first class Army Reserve, available for service in the field with the Army when required. This organisation cannot fail to be of advantage, as the efficiency of the men in their special work will be maintained by their daily employment in the Post Office, where they will have opportunities of becoming acquainted with the latest developments of the telegraph system. As members of the Post Office Volunteers, the men will obtain sufficient military training and knowledge of duties in camp to make them ready at once to fall into their position in the Army. The Post Office Volunteers have now 100 men of the Army Post Office and 50 of the Army Telegraph Office attached, and we hope this is the first step in utilising volunteers for any special duties of this nature.

POST OFFICE TELEPHONES.—In the House of Commons on Monday last Mr. Fawcett said the Post Office on the 31st March last had 783 subscribers to its systems of telephone exchanges for rentals amounting to £16,983 per annum. As it would take much time to ascertain the number of private wires rented from the Post Office which are worked by telegraph and telephone apparatus respectively, I am sorry I am not able to answer the hon. member's second question. If the telephone exchange lines of the department were provided by the private telephone companies at the same rentals the royalty payable would be £1,698 per annum. No royalty is payable to the Post Office in respect of private wires—*i.e.*, wires used for private messages, as defined by the Act of 1869, erected and maintained by persons outside the department. So far, therefore, as this business might be done by private individuals, no revenue would be received by the Post Office. The amount of royalties received by the Post Office in the year ended 31st December last from telephone companies for licenses to carry on business which has been legally decided to be telegraphic was £15,556. The original rate of percentage was 10 per cent., increased in a few cases of extension of radius. In reply to my hon. friend's last question, I may say that in new licenses the percentage is no greater, but a minimum royalty of £1 is payable.

UNDERGROUND ELECTRIC WIRES IN NEW YORK.—The Committee of Underground Communication have submitted their report, after a prolonged investigation and the examination of over six hundred patents, which they have classified. After stating the principal features of all the classes, and the objections to each, the committee gave at length a description of a form of construction by which several direct wires are provided with a common return wire, both the direct and return wires being wound in long spirals on a core of any material, so that the direct and return wires always occupy the same relative position to any external wire. As regards conduits, the committee state that the principal requirements are that it be cheap, watertight, have sufficient capacity, permit (without disturbing the pavement) the insertion, removal, and addition of wires, and allow access for repairs and testing. Terra-cotta thoroughly coated with asphalte is a cheap material, and when protected by an outer box or covering of creosoted wood is adapted for an underground conduit of the usual form. It is unaffected by changes of temperature, there is little or no difficulty in securing and maintaining tight joints, and if properly coated with asphaltum it is indestructible. In the matter of insulation of the conductors the committee are only able to say that the value and durability of an insulating material can only be determined by an actual use extending over many years. Of the numerous substances and compounds for which patents have been granted it is impossible to say or know, without experience, that they will or will not, in use, meet the requirements. On the whole we consider the report a very lame and unsatisfactory one.

THUNDERSTORM: ACCIDENTS THROUGH OVERHEAD WIRES.—About half-past one on Monday afternoon a thunderstorm broke over the metropolis. The black clouds which had been drifting across the sky during the latter part of the morning formed a thick pall, from which from time to time vivid sheets of lightning darted forth, followed by loud peals of thunder, and attended by a heavy fall of rain. The storm lasted for some time, and in the midst of it several telegraph wires crossing Blackfriars-road were snapped and fell. The wires recoiled and caught two women and a man, who were severely shaken, and removed to Mr. Smith's surgery. There were three tramcars passing at the time, and the passengers of the Brixton

Digitized by Google

159 car and the Greenwich car had a narrow escape of their lives. The two horses drawing the Clapham tram were thrown to the ground. At Updown, near Margate, at the height of the storm the lightning set fire to the haystacks in a farmyard belonging to Mr. Stokes. All the stacks, with one exception, together with the farm buildings, were destroyed, but the farmhouse and live stock fortunately escaped. At Cambridge several flashes of lightning were extremely vivid. One struck a house on the Vinery-road, Romsey Town, Cambridge, belonging to Mr. Shearman, and literally split it in two, inflicting very serious destruction of property, also smashing some extensive greenhouses. The family of Mr. Shearman, who were dining at the other end of the house, were uninjured. The fireplace of one room was forcibly driven outwards some distance. During the storm at Dover a waterspout was witnessed between Dover and the South Foreland. It was gradually drawn upwards and disappeared soon after, passing over in the neighbourhood of the castle.

Electro-chemical Researches on Nitrogen.—Mr. G. S. Johnson contributes a paper on this subject to a recent number of the *Chemical News*, of which the following abstract appears in the Chemical Society's *Journal* for this month:—"The author confirms the results of Thénard and of Berthelot as to the formation of ammonium nitrite by the action of the silent discharge on nitrogen gas in presence of aqueous vapour. He is of opinion that to render the nitrogen *active* the gas must be perfectly dry, and the electricity of high tension. The author has tried various experiments with nitrogen and hydrogen; with nitrogen, hydrogen, and oxygen; and with hydrogen and air in the Grove gas battery. The effect of the silent discharge on tubes of nitrogen in the gas battery circuit has also been studied, when the nitrogen is found to combine completely with hydrogen in proportion of 1 vol. to 3 vols. These results and others in which currents were observed between nitrogenised and hydrogenised platinised plates, the nitrogen in the platinised plates existing apparently in an electro-negative condition, are brought forward by the author as evidence of the duality of nitrogen. Other conclusions arrived at are that nitrogen and hydrogen can generate currents in Grove's gas battery which are inversely proportional to the internal resistance. The hydrogen always contracts, but if the external resistance is great and the internal small the volume of the nitrogen increases, but there is no combination between the nitrogen and hydrogen. When the internal and external resistance is reduced to a minimum combination takes place, and the hydrogen contracts much more rapidly than the nitrogen expands. Ammonia has been found in the acid over which air and hydrogen and nitrogen and hydrogen have been observed to contract."

Electrolysis.—According to the abstract in the Chemical Society's *Journal*, Herr Schucht has investigated the separation of a number of metals from their solutions electrolytically. Luckow (Abstr., 1880, 282) has shown that lead is separated from solution, preferably a nitric acid one, as peroxide, or this mixed with hydrated peroxide. It is only from strongly acid solutions that the whole of the lead separates as peroxide; from feebly acid and concentrated solutions the peroxide is mixed with a large proportion of metallic lead. The separated peroxide was found to contain more water when precipitated from a feeble acid solution than from a strongly acid one; the presence of much free alkali also increases the proportion of water. Solutions of thallium resemble those of lead; the metal being separated either entirely as sesquioxide, or mixed with a small proportion of metal, according to the quantity of free acid present. The thallium is separated from alkaline solutions partly as sesquioxide and partly in the metallic state. Silver is precipitated, in the absence of nitrates or free nitric acid, as metal only, whilst, in the presence of the above, a small proportion of silver peroxide, $Ag_2O_2$, is formed. Solutions of bismuth are decomposed by the current into metal and bismuthic acid, the latter appearing only gradually at the positive pole, whilst the peroxides of the former metals are formed from the commencement of the current. In the electrolysis of ammoniacal solutions of nickel and cobalt the sesquioxide appears at the positive pole, but its separation is prevented by excess of ammonia; the largest proportion of sesquioxide obtained by the author amounted to 3—3·5 per cent. of the amount of precipitated metal. Manganese is the only metal which is separated exclusively as peroxide from its solutions. The presence of organic acids, ferrous salts, and salts of chromium or ammonium prevent the formation of the peroxide and the red coloration due to permanganic acid. Selenium and tellurium are readily precipitated by the current, both from acid and alkaline solutions.

An Electric Mountain-Railway.—A correspondent of *The Times* writes as follows:—"A project has been formed, and will, in all probability, shortly be executed for uniting the Hôtel des Alpes, at Territet Chillon, and the Hôtel de Mont Fleury, which is situated on the steep mountain side immediately above Chillon, by an electric railway. The difference of altitude between the two hotels is 180 metres, and a few days ago the system which it is proposed to adopt was put to an experimental test. Rails of a gauge of 50 centimetres were laid on a part of the mountain for a length of 50 metres, and with a gradient of 30 to the 100. Between the rails is a rack for the reception of a toothed wheel, and at each end is a curve in order to show the advantage of the proposed system over the funicular system, which does not admit of the slightest curve. The waggon carries a dynamo-electric machine, which actuates by special gearing a toothed wheel on the axle in connection with the rack between the rails. An electric and an ordinary brake enable the conductor to modify the rapidity of descent at pleasure. The electricity was produced for the occasion, and in the first instance, by a dynamo-electric machine of five horse-power, actuated by a portable engine. This engine it is intended to replace eventually by a turbine, for which there is ample supply of water. The apparatus for the transmission of the electric force to the receiver on the waggon consists of copper cables laid between the rails and alongside the rack, and the electric contact is established through the intermediary of mechanical brushes in the usual way. The carriage, in which were seated two, three, and sometimes four persons, the whole, including the carriage, representing a weight of from 300 to 500 kilogrammes, went up the steep incline at the rate of from 1 metre to 2 metres per second, and the descent was completely controlled by the ingenious combination of the two brakes. In the event of the project being carried into effect, which depends to some extent on the approval of the Federal Government, the journey between the two hotels may be performed in seven or eight minutes. As, moreover, water is plentiful in Switzerland, there is no reason why every fashionable mountain should not have its own particular electric railway, and the time may come when idle or infirm tourists will ride luxuriously across the Mer de Glance and be carried on wheels half way up the Jungfrau and the Matterhorn. Already the people at Geneva, encouraged by the success of the experiment at Territet Chillon (Montreux), are proposing to utilise the waters of the Arve for the ascent of the Salève. But what will Mr. Ruskin say?"

Digitized by Google

## ELECTRO-CHEMISTRY.—INORGANIC.

BY DR. G. GORE, F.R.S.

(CONTINUED FROM PAGE 583.)

**Separation of Molybdenum.** — Mo. Atomic weight = 96. A cation. Sodium molybdate is not reduced by metallic tin. (Ullik, "Watts's Dictionary of Chemistry," Vol. VI., p. 832). From an ammoniacal solution of molybdic anhydride, by means of a separate current, molybdenum is completely and firmly deposited upon the cathode as molybdous oxide in coloured rings which thicken and become black. The first blue precipitate is molybdic molybdate, then follow molybdic and molybdous oxides. In acid solutions there is no deposit. In ammonium molybdate acidified with molybdic anhydride the precipitation is incomplete. (L. Schicht, *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 747 ; *Chem. News*, Vol. XLI., p. 280, and Vol. XLII., p. 331.)

Molybdic acid dissolves freely in pure dilute hydrofluoric acid, evolving a little heat. I electrolysed the solution both with a platinum and with a gas carbon anode and a current from ten large Smee's cells. The colourless liquid conducted freely, becoming instantly of an indigo blue colour at a platinum cathode. Gas was set free at each electrode, that from the carbon anode was the most abundant, and had a slightly chlorous odour. On stopping the current the deep blue film on the cathode quickly dissolved, and the liquid soon became colourless. During the action the cathode was several times removed and dipped into water, much blue matter dissolved, but the water became nearly colourless in half a minute, even without stirring, and however large the quantity of the blue matter was which dissolved in it.

I also fused some molybdic acid in a porcelain crucible, and passed a current through it from five Smee's elements, by means of a gas carbon anode and platinum cathode. It conducted freely. The action was rather strong at the anode, but little gas was set free. No gas was evolved at the cathode, but crystals quickly collected upon it in a large mass, which soon filled the entire solution and spread to the anode. The carbon was not disintegrated or dissolved. The cooled residue was a black mass of crystals. In a second trial with a current from 12 similar cells, and a platinum anode and cathode, much gas was set free at the cathode, and less from the anode, and the bluish black deposit formed upon the cathode. A large number of crystalline needles, from $\frac{1}{8}$th to $\frac{1}{4}$th of an inch long, stood out at right angles upon the surface of the cathode in the liquid. The deposit imparted a transient green colour to water.

Crystals of dioxide of molybdenum $Mo O_2$ quickly become covered with copper when immersed in a solution of cupric sulphate in contact with zinc. (Ullik, Watts's "Dictionary of Chemistry," Vol. VI., p. 832.)

For the electrolytic analysis of molybdenum compounds see E. F. Smith, *Chem. News*, Vol. XLIII., p. 6; and also *Jour. Chem. Soc.*, Vol. XL., 1881, p. 3.

**Separation of Lead.**—Pb. Electro-chemical equivalent $\frac{207}{2} = 103{\cdot}5$. A dyad cation. The deposition of lead by the simple immersion of zinc in a solution of nitrate or acetate of lead is a very old fact, and when the zinc is in the form of a spiral wire it constitutes the well known "lead tree." According to A. Cossa an alkaline solution of plumbic chromate is at once decomposed by aluminium, with deposition of lead and formation of chromic oxide. (Watts's "Dictionary of Chemistry," Vol. VII., p. 54.) Thallium deposits lead from a solution of plumbic acetate. (W. C. Reid, *Chem. News*, Vol. XII., p. 242.) Lead in contact with gold in acid or neutral, cold or hot, solutions of salts of lead, produces no deposit of lead. (Raoult, *Jour. Chem. Soc.*, Vol. XI., p. 646.)

**Electrolysis of Plumbic Nitrate.**—$Pb2NO_3$. Molecular weight = 331. A solution of this salt is slowly decomposed by contact with aluminium, and the lead deposited in crystals (A. Cossa, Watts's "Dictionary of Chemistry," Vol. VII., p. 54). Magnesium immersed in a solution of plumbic nitrate is quickly covered with lead powder, which quickly oxidises. (S. Kern, *Jour. Chem. Soc.*, 1876, Part I., p. 683). In a solution of hyponitrite, nitrate, or acetate of lead, zinc received a coating of lead by simple immersion, but antimony, bismuth, tin, lead, iron, nickel, copper, brass, German silver, silver, gold, or platinum did not. A solution of the nitrate yields by electrolysis with a separate current peroxide of lead at the anode.

**Electrolysis of Plumbic Fluoride.**—$PbF_2$. I fused some of this salt in a platinum crucible, and added some crystals of boron; vivid incandescence occurred, and melted lead was separated. The addition of crystals of silicon had a similar effect. Metallic antimony or copper did not liberate lead. By stirring the melted salt with an iron rod heat was evolved, the iron corroded, and lead was set free. The addition of zinc to the fused salt caused an explosion, and magnesium produced quite a dangerous detonation.

Beetz electrolysed this salt in a fused state by a separate current, and observed that a colourless gas was evolved from the anode, and lead set free at the cathode. (*The Chemist*, New Series, Vol. I., p. 253). G. J. Knox electrolysed it with an anode of charcoal and a cathode of platinum wire by means of a current from sixty voltaic cells. (*Phil. Mag.*, 3rd Series, Vol. XVI., p. 192). Fremy found it easily decomposed by a separate current; lead was deposited (*The Chemist*, New Series, Vol. II., p. 548). I melted 400 grains of the pure salt in a thick copper crucible, and electrolysed the liquid by means of a current from six Smee's cells, using a platinum wire anode, and a copper wire cathode. Conduction was copious; a bulky crust quickly formed upon the cathode, and advanced towards the anode in lumpy projections. A little gas appeared at the latter, but during a short time only. The deposit upon the cathode was not lead, nor was there any metal contained in a free state in it, nor in the saline mass, after action lasting one hour ; it was a mass of lead salt, brittle, and of a red-brown colour (like that of peroxide of lead) when cold. The conduction was very perfect, and the fused salt appeared to conduct without being decomposed. The anode was not corroded. I also electrolysed the fused salt in a deep, narrow, and thick copper cup, with an anode of gas carbon, during one and a quarter hour. The anode was corroded, and the metal liberated; action was copious, gas was evolved at the anode, and about seven or eight cubic inches were collected.

**Electrolysis of Plumbic Chloride.**—$Pb. Cl_2$. Molecular weight = 278. According to Commaille, magnesium deposits lead, together with much hydrogen, from a neutral solution of this salt (*Chem. News*, Vol. XIV., p. 188). Aluminium immediately deposits crystals of lead from it (A. Cossa, Watts's "Dictionary of Chemistry," Vol. VII., p. 54). According to Becquerel, if a piece of bright copper in contact with zinc be immersed in a solution of the chlorides of lead and sodium it becomes coated with lead. (*The Chemist*, Vol. V., p. 408.)

Faraday found that the proportion of lead deposited from its fused chloride to that of water decomposed by the same current was as 100·85 to 18. (Watts's "Dictionary of Chemistry," Vol. II., p. 439.) According to Buff, solid lead chloride conducts like a metal, *i.e.*, without decomposition, but rise of temperature *increases* its conductivity. (*Jour. Chem. Soc.*, 1876, Part I., p. 668.) Faraday found that by passing a current through the melted salt, chlorine appeared at the anode and lead at the cathode.

**Electrolysis of Plumbate of Potash.**—Metallic zinc or tin, but not iron, becomes coated with lead by simple immersion in a solution formed by dissolving litharge in a boiling hot solution of caustic potash.

Haeffelly deposits lead upon copper or brass by immersing them in contact with a piece of tin in a hot alkaline solution of oxide of lead. The tin dissolves in the form of an alkaline stannate, and the lead is deposited in a spongy state. (*Chem. News*, Vol. VI., p. 163.) I connected together a wire of zinc and one of platinum, and immersed the pair in a solution of litharge in strong aqueous ammonia; both wires became coated with a black deposit in a few minutes. By contact with air, the moist deposit became yellow, and was apparently

Digitized by Google

reconverted into litharge. F. Weil coats copper, iron, and steel with lead, by dissolving a salt of lead in a strong solution of potash or soda, and immersing them in the liquid in contact with zinc; the deposit, however, contains zinc. To obtain it pure, the piece of zinc is placed in the alkaline lixivium in a porous cell, and the cell immersed in the lead solution, the zinc being connected with the copper, &c., by a wire (*Chem. News*, Vol. XIII., p. 2).

**Electrolysis of Plumbic Acetate.**—According to A. Cossa, aluminium slowly deposits lead in crystals from a solution of this salt (Watts's "Dictionary of Chemistry," Vol. VII., p. 54). By a separate current, this solution yields peroxide of lead at the anode.

**Formation of Peroxide of Lead.**—According to W. Wernicke, an alkaline solution of the tartrate of lead and sodium, with platinum electrodes and a current from two Daniell's cells, yields a black deposit of peroxide of lead upon the anode; and a solution of one part of plumbic nitrate and eight of water gives a similar deposit by such treatment (*Jour. Chem. Soc.*, Vol. IX., p. 306; *Chem. News*, Vol. XXII., p. 240).

Nobili, in the year 1826, discovered that if a solution of acetate of lead be electrolysed by means of a large sheet platinum anode, and a platinum wire cathode, a deposit is formed upon the positive plate; and that if a polished steel plate be employed as the anode, with a current from four or six Grove's cells, the deposit is in the form of a thin film, and exhibits all the colours of the spectrum; and by placing the positive plate horizontally beneath the vertical negative wire the colours are in the form of rings, the centre of which is the wire, and are arranged in the order of the chromatic scale. These colours are known as "Nobili's rings." Becquerel, Gassiot and others have, by varying the strength of the battery, and of the solutions employed, and interposing non-conducting patterns between the anode and cathode, and by using cathodes of different shapes, obtained effects of great delicacy and beauty. Salts of other metals, such as bismuth, silver, nickel, cobalt, manganese, &c., which yield deposits of peroxide of the anodes, may be employed instead of those of lead. Becquerel prepared his plumbic solution as follows:—Dissolve 200 grammes of caustic potash in two quarts of distilled water, add 150 grammes of litharge, boil the mixture half an hour, allow it to become clear, take the clear portion and dilute it with its own bulk of water (*The Chemist*, Vol. IV., p. 457). The solution is used cold, and is rapidly deprived of its metal, because lead is deposited upon the cathode at the same time.

By this means may be imparted to polished surfaces of metals all the richest colours of the rainbow. "They commence with silver blonde, and progress onwards to fawn colour, and thence through various shades of violet to the indigo and blues; then through pale blue to yellow and orange; thence through lake and bluish lake to green and greenish orange and rose orange; thence through greenish violet and green to reddish yellow and rose lake, which is the highest colour on the chromatic scale" (Walker's "Electrotype Manipulation," Part 11, 16th edition, p. 40). Too great a strength of the current covers all the tints with an uniformly dark brown coating. The deposits, if properly prepared, resist friction well. The process is termed "Metallo-chromy."

Metallo-chromy effected by means of a solution of oxide of lead in caustic soda, or potash, is largely employed in Nuremberg to ornament metallic toys (Wagner's "Technology," p. 117). Bells are similarly coloured in France, and the hands and dials of watches in Switzerland.

**Electrolytic Analysis of Compounds of Lead.**—See *Jour. Chem. Soc.*, Vol. XXXVIII., 1880, p. 284., Vol. XLII, 1882, p. 1,320; *Chem. News*, Vol. XXXV., p. 264; Vol. XLVI. p. 106; Watts's "Dictionary of Chemistry," Vol. VIII., Part 1., p. 712, Part 2, p. 1,168.

## THE INDUCTION OF CURRENTS IN CORES.

BY OLIVER HEAVISIDE.

(CONTINUED FROM PAGE 586.)

[*Errata in last.*—p. 585, line 6, *for* core *read* coil; in the 2nd of equations (22) *for* $x + read + x$; in equations (26) *dele* accents on right side.]

*Waves of Magnetic Force.*—From equations (25) and (24) we see that the magnetic induction due to the oscillatory coil current travels into the core from its boundary in waves, decreasing rapidly in amplitude as they progress. It is not, however, a case of real wave propagation, but of diffusion. To get an idea of the lengths of waves at given speeds, let in (25) the constant B = 0, and A = 1, making

$$H = M \sin nt + N \cos nt.$$

At the moment $t = 0$, or at any succeeding moment making $\sin nt = 0$, we have $H = N$, where N is given in (24). N is zero at the axis, positive up to a certain distance, then negative, and so on until the boundary is reached, after which there are no more reversals of sign. The range of N on each side of zero increases fast with $r$. By inspection, the function N vanishes for the first time when its second term, disregarding its sign, is a little greater than the first, or $xr^2$ a little greater than 24, say 25. Now here $x = 4\pi\mu n/\rho$, so

$$4\pi\mu n r^2 = 25\rho$$

makes N vanish. Let the core be of copper, for which $\rho = 1700$ (*i.e.*, 1·7 microhm per c.c.) and $\mu = 1$. Also put $n = 2\pi v$, $v$ being the number of waves per second. Then we have

$$4\pi \,.\, 2\pi v \,.\, r^2 = 25 \,.\, 1700 \quad \text{or} \quad vr^2 = 530.$$

Thus, if there are 530 waves per second, N vanishes at a distance of 1 cm. from the axis, and as it also vanishes at the axis, the length of the first semi-wave of magnetic force in the core is 1 cm. As it varies in general inversely as the square root of the speed, we may get as many waves as we like into a core by increasing its diameter and the speed. But we cannot get shorter waves at the same speed than in copper in any other material except iron, and perhaps other magnetic metals, on account of $\rho$ being least for copper.

But let the core be of iron. Its specific resistance is about 10,000, thus considerably reducing $x$, as compared with copper. On the other hand $\mu$ is usually a large number. Its value is so eminently variable that it is difficult to know what value to take. But $\mu = 100$ in good soft iron is probably not very far over or under a fair average. This makes

$$x = \frac{8\pi^2 \,.\, 100 \,.\, v}{10000} = \frac{8v}{10}$$

so

$$vr^2 = \frac{250}{8} = 31$$

makes N = 0 for first time, and thus a speed of only 31 waves per second will make the length of the first semi-wave of magnetic force = 1 cm. The speed $v = 530$ mentioned in the case of a copper core above will reduce it to $\frac{1}{4}$ cm.

At the times making $\cos nt = 0$, we have H = M; H is then unity at the axis, and 0 for the first time at such a distance as makes $xa^2$ a little over 8. This will give only half a semi-wave.

*Amplitude of Magnetic Force.*—The maximum value of H at any point in the core varies as $(M^2 + N^2)^{\frac{1}{2}}$. By squaring the two expressions in (24) and adding the results we find the following series for $M^2 + N^2$:—

$$M^2 + N^2 = 1 + \frac{2y}{2^2 4^2}\left(1 + \frac{3y}{6^2 8^2}\left(1 + \frac{3\frac{1}{3}y}{10^2 12^2}\left(1 + \frac{3\frac{1}{2}y}{14^2 16}\right.\right.\right.$$
$$\left.\left.\left.\left(1 + \frac{3\frac{3}{5}y}{18^2 20^2}(1 + \ldots \quad . \quad . \quad . \quad . \quad . \quad . \quad (30)\right.\right.\right.$$

where we employ the brackets to show readily the degree of convergence of the series for a given value of $y$, which stands for $x^2a^4$, the quantity whose powers appear in the expressions for M and N. Every term being positive, it is verified that the amplitude increases continuously from the centre outward.

Digitized by Google

Compare the amplitudes of the magnetic force oscillations at the centre, at $\frac{1}{2}$ cm. and at 1 cm. First in a copper core, for which, as above, $y = 25^2$ about for 1 cm. and $25^2/4^2$ for $\frac{1}{2}$ cm. With $y = 24^2$ we find

$$M^2 + N^2 = 1 + 18\left(1 + \frac{3}{4}\left(1 + \frac{2}{15}\left(1 + \frac{9}{224}\left(1 + \dots\right.\right.\right.\right.$$
$$= 34{\cdot}37 = (5{\cdot}8)^2.$$

And with $y = 24^2/4^2$ we get

$$M^2 + N^2 = 1 + \frac{18}{16}\left(1 + \frac{3}{64}\left(1 + \frac{2}{240}\left(1 + \dots\right.\right.\right.\right.$$
$$= 2{\cdot}18 = (1{\cdot}47)^2.$$

Thus, we find the amplitudes at the centre, at $r = \frac{1}{2}$ cm., and $r = 1$ cm., to stand in the ratios

$$1 : 1{\cdot}47 : 5{\cdot}86,$$

being almost exactly four times as great at the double distance. (We took $24^2$ instead of $25^2$ to simplify the fractions, thus making the distances a trifle smaller.)

In the iron core we shall of course have exactly the same proportions with the same values of $y$, but on account of the largeness of $\mu$, whose square appears in $y$, the distances will be much less, or they may be the same with a lower speed to suit. We see from the great rapidity of increase of the amplitude that in a large core, especially if it be of iron, the magnetic induction reaches the centre in comparatively small strength, quite insignificant in fact if the speed be such as to cause there to be several waves in the core at once. The inner small magnetic force on the action at a distance hypothesis is of course due to the magnetic force due to the coil current being nearly cancelled by that due to the exterior core currents. In the Maxwellian view of the matter the magnetic induction is a flux; it, or the molecular disturbance corresponding to it, travels in a conductor, diffusing itself according to the same laws as heat, with this remarkable difference, that the better the conductor the slower the diffusion. In the present case, the magnetic induction in the core being everywhere directed parallel to its axis, the diffusion takes place radially from the coil to the axis of the core and back.

*Heat in Core and in Coil.*—Let W and $w$ be the heats per second in the coil circuit and in the core, when the oscillatory current passes in the coil. By Joule's law the rate of generation of heat in the coil circuit is $R\Gamma^2$, but since $\Gamma$ is a simple harmonic function of the time, this amounts to only

$$W = \tfrac{1}{2}R\,(\Gamma)^2 \text{ per second} \quad . \quad . \quad . \quad . \quad (31)$$

where $(\Gamma)$ is the amplitude of $\Gamma$. Hence by equation (29), the last equation on p. 586,

$$W = \frac{\frac{1}{2}R}{(4\pi N)^2}\,(A^2 + B^2)\,(M^2 + N^2) \quad . \quad . \quad . \quad (32)$$

where the boundary values of M and N are to be used.

In the core we have, similarly, $\rho\gamma^2$ = rate of generation of heat per unit volume, or $\frac{1}{2}\rho\,(\gamma)^2$ per second, $(\gamma)$ being the amptitude of $\gamma$; and, summing this up throughout the core, we get

$$w = \tfrac{1}{2}\rho l \int (\gamma)^2 2\pi r dr = \pi\rho l \int (\gamma)^2 r dr.$$

Here, by equations (10) and (25) we have

$$(\gamma)^2 = \frac{1}{(4\pi)^2}(H')^2 = \frac{1}{(4\pi)^2}(A^2 + B^2)\,(M'^2 + N'^2).$$

Hence

$$w = \frac{\pi\rho l}{(4\pi)^2}\,(A^2 + B^2)\int (M'^2 + N'^2)\,r dr \quad . \quad . \quad (33)$$

The integration is easily performed. Integrate one of the M's and one of the N's; thus,

$$\int (M' \cdot rM' + N' \cdot rN')dr = MrM' + NrN$$
$$- \int \left\{ M\frac{d}{dr}(rM') + N\frac{d}{dr}(rN') \right\} dr$$

Here the quantity under the integral sign on the right vanishes, as may be seen by equations (26); so taking limits $r = 0$ and $r = c$ we bring (33) to

$$\left.\begin{aligned} w &= \frac{\pi\rho lc}{(4\pi)^2}(A^2 + B^2)(MM' + NN') \\ &= c\pi\rho l(N\Gamma)^2\frac{MM' + NN'}{M^2 + N^2} \end{aligned}\right\} \quad (r = c) \quad . \quad . \quad (34)$$

In the last expression for the core heat per second in terms of the coil current, with A and B removed, we have a fraction to consider. The numerator is one half of the differential coefficient of the denominator, the expression for which is given in equation (30). Hence we find, by differentiating (30) with respect to $r$, the value of the numerator to be

$$MM' + NN' = \frac{y}{16r}\left(1 + \frac{6y}{6^2 8^2}\left(1 + \frac{5y}{10^2 12^2}\right.\right.$$
$$\left.\left(1 + \frac{4\frac{2}{3}y}{14^2 16^2}\left(1 + \frac{4\frac{1}{2}y}{18^2 20^2}\left(1 + \dots\right.\right.\right.\right. \quad . \quad (35)$$

where $y$ stands for $x^2r^4$.

Now, when $y$ is not too large we may take only the first terms in this series, and in that for $M^2 + N^2$, *i.e.*, take

$$M^2 + N^2 = 1 \qquad \text{and} \qquad MM' + NN' = \frac{y}{16r} = \frac{x^2c^3}{16}$$

putting $r = c$. Further, put for $x$ its full expression $8\pi^2 r\mu/\rho$, and (34) becomes

$$w = \frac{4\pi l}{\rho}\left(\pi^2 c^2 \mu v N\right)^2 \left(\Gamma\right)^2 \quad . \quad . \quad . \quad . \quad (36)$$

From this we see that the core heat, with the same coil current per unit length of core (*i.e.*, $N\Gamma$), varies directly as the conductivity of the core, as its length of course, as the square of its section, as the square of its permeability, and as the square of the speed. That it should vary as the square of the permeability will be understood on remembering that the inductive E.M.F. in the core, and therefore the current, varies as the time rate of decrease of the induction, which is $\mu$ times the magnetic force, which makes the square of the current, and therefore the heating, vary as $\mu^2$. Also we see at once how immensely greater the heating must be in iron than in copper, the high conductivity of the latter being little set off against the large value of $\mu^2$. These conclusions require $y$ to be small enough to make the second term in the expansion for $M^2 + N^2$ small compared with unity. The full expression for the core heat is got by multiplying the expression in (36) by Y where

$$Y = \frac{1 + \frac{6y}{6^2 8^2} + \frac{30y^2}{6^2 \dots 12^2} + \dots}{1 + \frac{2y}{2^2 4^2} + \frac{6y^2}{2^2 \dots 8^2} + \dots}$$

by (35) and (30). Since the denominator increases faster than the numerator, the heat becomes less than is represented in equation (36), and in fact a small fraction thereof when $y$ is made large.

We may easily make the core heat as great as the coil heat, even if the core is very small and non-magnetic, and no great speed is required either, whilst with iron cores it may be hundreds of times as much. The heats in the core and in the coil being associated, it will be desirable to compare the core heat, not with the heat in the whole coil circuit, but in the coil only. Using, then, the equation (9) for the coil resistance, viz. :—

$$R = (2Nc_1)^2\frac{\rho_1 l}{b}(2a + b) \quad . \quad . \quad . \quad . \quad . \quad (9)\ bis.$$

we find by (36)

$$\frac{w}{W} = \frac{2\pi b\,(\pi^2 c^2 \mu v)^2}{c_1^2 \rho\rho_1 (2a + b)} \quad . \quad . \quad . \quad . \quad . \quad (37)$$

*Example* 1.—Now let the coil wire and the core be of copper, $\rho = \rho_1 = 1{,}700$, and $\mu = 1$, and take $c_1 = 1$, which is near enough. Also let the core fill the coil opening, making $a = c$, and let this be 1 cm., and the depth $b = 2$ cm. Then

$$w\ W = \pi \cdot 100r^2 \cdot 1700^2 = r^2\ 9{,}000 \text{ say.}$$

## THE ELECTRO-CHEMICAL EQUIVALENT OF SILVER AND THE ABSOLUTE ELECTROMOTIVE FORCE OF CLARK CELLS.

BY LORD RAYLEIGH, D.C.L., F.R.S.

The investigations upon this subject which have been carried on by Mrs. Sidgwick and myself during the last year and a half, though not yet quite finished, are so far advanced that no doubt remains as to the general character of the results; and as these results have application in the daily work of practical electricians, it is thought desirable to communicate them without further delay.

The currents are measured by balancing the attraction and repulsion of coaxal coils against known weights, as described before the British Association in 1882, a method which has fully answered the favourable expectations then expressed. To what was said on that occasion it will be sufficient for the present to add that the readings are taken by *reversal* of the current in the fixed coils, and the difference of weights thus found (about 1 gram) represents the double force of attraction, free from errors depending upon the connections of the suspended coil, and other sources of disturbance.

The difficulties which have been experienced, and which have been the cause of so much delay, have related entirely to the behaviour of the silver voltameters, of which never less than two, and sometimes as many as five, have been included in the circuit of the measured current. In order to render the deposit more compact, and thus to diminish the danger of loss in the subsequent manipulations, *acetate* of silver was added in the earlier experiments to the standard solution of nitrate. Experience, however, has shown that the principal risk is not in the loss of metal, but in the obstinate retention of salt within the fine pores of the deposit, leading to an over estimate of the amount. When the texture is very compact this danger increases, and deposits from a solution containing acetate are often decidedly too heavy, even after the most careful and protracted washings. On heating to low redness a portion, at any rate, of the retained salt is decomposed, $NO_3$ is driven off, and a loss of weight ensues. With pure nitrate, to which we finally recurred, the risk is much less.

The actual weights of deposited silver were usually from 2 to 3 grms., and, so far as the mere weighings are concerned, should have been correct to $\frac{1}{10000}$. Discrepancies three or four times as great as this are, however, actually met with, whether due to retention of salt or to loss of metal it is difficult to say. The final number, expressing in C.G.S. measure the electro-chemical equivalent of silver, is a little lower than that ($1{\cdot}119 \times 10^{-2}$) given on a previous occasion (Cambridge *Proceedings* for November 26, 1883). It approximates closely to $1{\cdot}118 \times 10^{-2}$, and is thus in precise agreement with the number announced within the last few weeks by Kohlrausch, viz., $1{\cdot}1183 \times 10^{-2}$. Its substantial correctness can therefore hardly be doubted, more especially as it does not differ very much from the number (1·124) obtained by Mascart. In terms of practical units, we may say that the ampere current deposits per hour 4·025 grms. of silver.

When we are provided with means for the absolute measurement of currents, the determination of electromotive force is a very simple matter if we assume a knowledge of absolute resistance. A galvanic cell is balanced against the known difference of potentials generated by a known current in traversing a known resistance. The difficulty relates entirely to the preparation and definition of the standard cells. A considerable number of Clark cells have been set up and tested at intervals during the last six months, and their behaviour has been satisfactory, the extreme range (after the first ten days) not much exceeding $\frac{1}{1000}$. A modified form of cell in which the solid zinc is replaced by an amalgam is at present under trial.

In Mr. Latimer Clark's own determination the B.A. unit is assumed to be correct, and the E.M.F. of the cell at 15°C. was found to be 1·457 volt. *On the same assumption*, we obtain the not greatly differing value 1·453 volt. If we take the true value of the B.A. unit as 9·867 ohms, 1·453 will be replaced by 1·434.

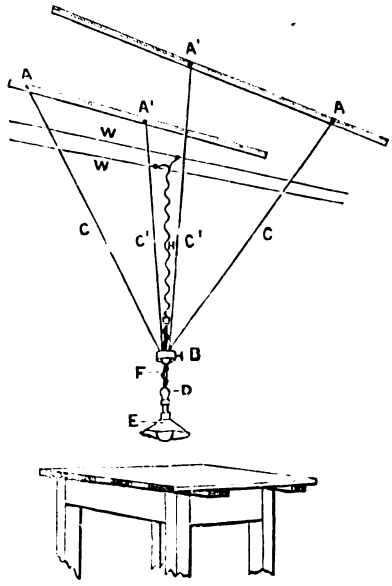
Experiments are also in progress to determine in absolute measure the rotation of the plane of polarisation of light in bisulphide of carbon under the action of magnetic force. Of the results obtained by Gordon and Becquerel, differing by about 9 per cent., our preliminary measurements tend rather to confirm the former.

---

## ELECTRIC LIGHT IN THE DRAWING OFFICE.

BY PROFESSOR J. A. EWING, OF UNIVERSITY COLLEGE, DUNDEE.

In the lighting of a drawing office it is of great importance to place the lamps in such positions that they will not cast shadows from the working edges of T-squares, set-squares, and other tools. If the light is localised over every drawing board, as of course it ought to be, this condition can be satisfied only by supporting each lamp so that it may be moved over all parts of the board. A pedestal support is seriously in the way, and the right plan evidently is to hang the lamp from above, but in a manner which will leave it two degrees of freedom to move horizontally. This has been very successfully done in the drawing-class room of this college on a plan suggested by my assistant, Mr. Thomas Reid, and shown in the sketch.



An incandescent lamp is carried at the foot of a rod, F, which depends from a small wooden block, B. The block is hung by two cords, $c\,c$, $c'\,c'$, from four points in the ceiling, A A A′ A′. Each of the two cords passes down and up through two vertical holes in the block, the two cords crossing each other on its lower face. This permits the block to be moved easily to any part of a surface as extensive as the spread of the points of support in the ceiling, the cords slipping through the block as it is moved, while their friction serves to keep it from returning of itself after being displaced. Further, the lamp can be raised or lowered by sliding the rod F up or down in the block B, in which it is secured by a pinching screw. A small weight at D keeps the rod vertical. A stout paper cone over the lamps reflects the light downwards, and screens the eyes of the draughtsman. The current reaches the lamp by a double flexible conductor, H, from two main leads, W W, which are thick bare copper wire stretched tightly across the room from wall to wall above a row of drawing tables at a height which keeps them clear of the suspension cords when a lamp is displaced. Each man has his own table and lamp, and is independent of his neighbours. The lamps are Swan's 100 volt of 20 candles, but a smaller power would suffice, as no light is wasted in illuminating spaces where it is not wanted. Over other tables ranged along the

Digitized by Google

walls the lamps are carried by double-jointed brackets, ending in collars through which rods similar to F slide. The system has been in use for some months. Its introduction brought about a very striking improvement in the air of the room, which the burning of much gas had formarly made almost intolerable. We now have pure air and a far better light.

## THE ELECTRIC CONFERENCE.

The International Conference on Electrical Units has concluded its labours by adopting the following resolutions, which, according to M. Cochéry, will be productive of great results to electrical industry and to humanity generally :—

I. *Electrical Units, properly speaking.*

1st Resolution.—The legal ohm is the resistance of a column of mercury one square millimetre in section and 106 centimetres in length, at the temperature of melting ice.

2nd Resolution.—The Conference expresses the hope that the French Government will be good enough to transmit the above resolution to the various States, and also recommends its international adoption.

3rd Resolution.—The Conference recommends the construction of primary mercurial standards, in conformity with the resolution last adopted, and the simultaneous use of secondary sets of resistances constructed of solid alloys, and frequently compared with each other, and with the primary standard.

4th Resolution.—The ampere is the current, which in absolute measure is ten to the power of *minus* one electro-magnetic units.

5th Resolution.—The volt is the electromotive force which maintains a current of one ampere in a conductor having a resistance of one legal ohm.

II. *Electric Currents and Lighting Conductors.*

1st Resolution.—It is to be desired that the results of the observations collected by the various administrations should be sent each year to the International Bureau of Telegraphic Administrations at Berne, which will make an abstract of them, and will communicate this abstract to the Governments.

2nd Resolution.—The Conference expresses a wish that observations upon earth currents may be carried out in all countries.

III. *Standard of Light.*

Resolution.—The unit of each simple light is the quantity of light of the same kind which is emitted at right angles to itself by a surface, measuring one square centimetre, of molten platinum at its temperature of solidification. The practical unit of white light is the quantity of light normally emitted by the same source.

# CORRESPONDENCE.

## THE THEORY OF MAGNETISM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : When Professor Hughes says, as he has said, "I must admit that my paper was not clearly written," he bears testimony to the frankness with which a man of science will admit an error when such is made evident to him. I beg to thank Professor Hughes for the courteous character of his letter in this day's *Electrician*, and to assure him that I shall be equally ready to forego or modify my conclusions, which are the outcome of considerable experimental work, when it has been proved to me that such conclusions are erroneous. In the meantime, with your permission, Mr. Editor, and the implied concurrence of Professor Hughes, we will endeavour to eliminate truth from error in the pages of *The Electrician*.

It appears to me, however, that the differences are very unimportant, for Professor Hughes refers magnetic phenomena to the inherent polarity of matter, plus, as I understand, a current of electricity, whilst I say that electricity and magnetism are different manifestations of one force, and that the phenomena of magnetism are the outcome of the inherent polarity of matter giving direction to the energy of the earth.

We will now more particularly consider the main point of difference in the theory of Professor Hughes and myself, viz., motion or no motion.

Professor Hughes describes it in the following words :—"The only motion, therefore, is during a change of state or polarity. If there is constant polarity there is no consequent motion of the molecules ; in fact, the less motion of any kind that it can receive the more perfect its retention of its previous position. Consequently constant magnetism cannot be looked upon as a mode of motion neither vibratory nor rotary; it is an inherent quality of each molecule, similar in its nature to chemical affinity, cohesion, or its power of crystallisation."

Here Professor Hughes does not recognise the current of electricity.

My letters to *The Electrician* on "What is Electricity ?" to which I have already referred, show that as regards the inherent properties of matter, from which I do not except magnetic polarity, I am quite of the same opinion as Professor Hughes. Nevertheless, I regard magnetism as a force and mode of motion, and were it not both, magnetism could not, in my humble opinion, exhibit the phenomena which it does, more especially attraction and repulsion.

There is surely a considerable difference between the inherent qualities of matter and the manifestation of those qualities. The former may exist without being apparent ; the latter may depend upon some *motion* rendering them evident to our senses. To make this clear we must remember that a production of a sensation is the result of some force impressed upon a nerve, and that this force is then transmitted to the sensorium by the nerve in a similar, if not identical, manner to the mode in which impressions are conducted by Professor Hughes's beautiful magnetic balance, or by an ordinary telephone or telegraph wire.

My investigations go to prove that the manifestation of magnetic phenomena is always the result of kinetic energy, and I hope shortly to be enabled to conduct some experiments which will clearly establish the fact, if the fact really requires further experimental demonstration.

The earth is the great parent of all magnetism with which we have to do, and we will therefore consider the earth as a magnet, and why it exhibits the phenomena.

To my mind it appears impossible to conceive of the earth as a magnet, except in connection with its motion. How does Professor Hughes's theory with regard to magnetism without constant motion tally with the magnetic condition of the earth, which is always undergoing such rapid motion, mutation, &c. ? Are the magnetic manifestations of the earth in any way capable of being separated from the peculiar modes of motion which the earth performs, or, are they not ? That is to say, are the inherent qualities of matter rendered evident by the motion of the earth, or are they not ? It is difficult to conceive what would take place were the motion of the earth to cease ; but we can imagine that in that case all gravity must cease, and that the particles would resume the ethereal state. Unquestionably gravitation as the basis of motion is as essential to the existence of matter as the particles, and if so, the direction which the kinetic energy assumes whilst traversing the matter must be determined by the resistance of the matter, which, in other words, means the power which the matter possesses of retarding the force.

It commends itself to my judgment that every investigation into the nature of magnetism is bound to recognise that artificial magnetism is inseparably connected with terrestrial magnetism. For instance, all matter and ether, according to Professor Hughes and Faraday, is pervaded with magnetic force. Now, my investigations into artificial magnetism led me to consider terrestrial magnetism, and if the artificial is any guide to the natural, then all terrestrial magnetic phenomena are, as I pointed out in my last letter, the outcome of the mode in which matter transmits the kinetic energy of the earth. Thus iron and steel, and other magnetic forms of

Digitized by Google

matter, would cause this kinetic energy to be thrown off from the bar or earth with the manifestation of lines of force, whilst as copper and other diamagnetic bodies offer but little resistance, the kinetic energy continues its course without the manifestation of any visible phenomena. The former magnetic state may be illustrated by a jet of water projected with great force against a stone wall, the latter by the continuous and uninterrupted flow of the same water through the pipe or tube. It is true that in the case of magnetism the lines of force are not necessarily attended with any visible motion of particles, but the motion is made visible when the force impinges upon bodies, such as particles of steel or iron, which offer resistance to the force; then the particles turn so as to permit the force passing in the direction which offers the least resistance. Now, although when that direction has been assumed, as in the case of the compass needle to which Professor Hughes refers, motion of molecules is by no means necessary; still molecular rotation could continue, as I think I have shown, without any visible motion. However this may be, I hope, before I close this letter, to show clearly that all magnetic phenomena are simply a display of terrestrial kinetic energy.

With this object in view, I shall now direct attention to the earth's motion, and show that this is absolutely due to external impressed force, without which force motion, by what is called inertia, could not take place.

The term "vis inertia," literally the force of inactivity, was employed by Newton (invented by Kepler) to signify the power implanted in all matter by which it resists any change endeavoured to be made in its state, that is, the power by which it becomes difficult to change its state of rest or motion.

A distinction is made between vis inertia and inertia, the former signifying the resistance itself which is given by a body to any force, and the latter merely the property by which resistance is given.

The property of matter which is set forth in the law of inertia (Newton's "First Law of Motion") is, however, simply absolute passiveness (Rodwell's "Dictionary of Science.")

The doctrine of rotation by inertia is illustrated in the following manner:—Suppose a ball perfectly hard (that is, perfectly incompressible and unchangeable in shape) and perfectly smooth were bowled along the margin of a planet also perfectly hard and smooth, and without the resistance of any atmosphere or surrounding medium, then the projected ball would roll around that planetary sphere for ever (*Op. Cit.*).

With the above definitions of the doctrine of inertia we cannot fail to understand the doctrine, or to perceive that, whilst stating the effects of certain properties of matter, it gives no cause for the existence of the properties, that is, why bodies are capable of exerting resistance. It therefore seems most desirable that the precise manner in which matter acquires its properties should, as far as possible, be ascertained.

It appears to me that we are justified in assuming that matter in all its forms consists of particles which have been formulated from the ether by compression from without, or by attraction from within, probably both.

The nebular theory supports the view that the earth and the celestial bodies in general were formed by compression or condensation from without. Clerk-Maxwell goes further, and says that the different forms of matter manifest their various phenomena owing to the mode in which the particles have been combined. Now, as the smallest particles of any substance are identical in their physical characteristics with the largest masses of the same substance, and gravitation and the magnetic axis of power are most marked in the line of the greatest density, and the line in which matter transmits force is peculiar to each description of matter, there appears to be good grounds for assuming Clerk-Maxwell was correct.

We further know that, if the compressing force were removed, the expansion of particles would correspond with the degree to which pressure was relieved; consequently we cannot, as it appears to me, avoid the conclusion that the force which is inseparably combined with matter as an element of its constitution is a constant force, and that this force has been so exerted that the invisible ether, which is matter devoid of any recognisable characteristics owing to its extreme tenuity, has been converted into masses of great density, the degree of which pressure can be imagined when we can realise the change in bulk.

A little consideration, I think, renders it evident how this becomes a source of motion.

In the hypothetical ball of inertia we have to deal—

(1) With a perfect sphere, which, from a mathematical point of view, is a perfect system of points.

(2) With one of the perfectly hard points of this sphere which is resting upon another similar mathematical point.

(3) We recognise that the centre of gravity of such a sphere must correspond with the mathematical point upon which the sphere rests, and is therefore bound to be of the most unstable character, ever changing as one point upon which the sphere rests is changed for another.

We therefore perceive that this so called force of inertia is identical with the force of gravity, for if A represent a sphere of matter resting upon a mathematical point, and B is the force which combined the particles and converted them into a sphere, there must be a centre of gravity to such matter which we will call C.

Now it is evident that each of the three elements is essential to the existence of any material system, and that the compressing force is bound to continue in operation, or the system would vanish into ether, and cease to exist.

It is equally clear that any impressed force acting upon the sphere is bound to impart motion by gravity, which force being, as is well known, in proportion to the mass, prevents the mass exerting any force resultant of some external force.

We further perceive that, according to the laws of motion, the direction of motion must accord, other things being equal, with the direction of the impressed force; that is to say:—(1) If the force be applied to such a mass in a perfectly straight line, and with mathematical accuracy upon a central point, then the sphere will move forwards in a straight line; but (2) if the force be applied to such a mass a little above the central point, then it would be an oblique force, and axial rotation in a straight line would ensue; but (3) if force were applied a little to one side as well as above the central point, then there would be rotation of an ellipsoid character, the degree of the ellipse being regulated by the extent of the lateral departure from the central line.

It is also obvious that the same disposition to change of motion would result from unequal resistance being offered to the impressed force by the body in motion.

In making an application of this principle to the motion of the earth we find we have not to deal with such a hard, smooth, and incompressible mass of matter as hypothetically suggested, for (1) the earth's crust is very compressible, and has been compared by a considerable authority to a mass of jelly. (2) The surface is more or less uneven. (3) As a resisting medium it is very diversified. (4) The sun's energy, which in the shape of light and heat acts upon it as impressed force, penetrates not only the atmosphere, but—in intertropical regions especially—* every portion of the mass, and is refracted in the act, the degree of refraction being determined by the structure of the matter. (5) Magnetic polarity is displayed over the whole surface of the earth, but especially at the magnetic poles, and as this magnetic polarity is instantaneously affected by solar disturbances the knowledge we possess of the mode in which motion of matter affects such disturbances assures us of the intimate material relations which subsist between the sun and the earth, and gives us strong presumptive evidence that the magnetic relations between the earth and the sun alone would be quite sufficient to prevent the earth's rotation by inertia as described above. (6) I believe I am quite right in stating that the force of gravitation is unequal on the sunward and sunless sides of the earth. Under such circumstances the centre of gravity must be constantly changing from such cause.

If, then, inertia is absolute *passiveness* I think I have shown (1) that the earth does not in any one respect accord with the

* There is no rule without an exception, and the exception is found in tropical mountains, which from their inclination to the mass give an oblique direction to the impressed force.

Digitized by Google

condition of the hypothetical ball by which motion by inertia is said to be maintained. (2) That the motions of the earth are bound to take place under the continued exercise of that force which compressed the ether, and by such compression gave character and gravitation to matter. (3) That the term inertia is unscientific, because it is not expressive of a condition of matter which ever exists, more especially when considered in relation to the earth or one of the celestial bodies. Certainly if matter is only kept in its characteristic state by great pressure from without, or attraction from within, the matter cannot be impassive, or the pressure would not be required to prevent it once more resuming the form of ether. We might as well speak of impassive force, and take magnetic force as an illustration of the principle. Matter can only be regarded as impassive in a relative sense; it is the effect of a cause, and therefore to ascribe the motion of the earth to inertia is to substitute an effect for a cause.—Yours, &c.,

RICHARD C. SHETTLE.

## ELECTRIC CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Owing to my absence from town your issue of 26th ult., containing the notes of Mr. H. M. Arnot on the above subject, has been delayed in reaching me.

I venture to think that if Mr. Arnot looks once more into my table he will see that I fully recognise the importance of taking into consideration the length of the conductor when fall of potential is the question, inasmuch as I have not only given columns showing what the potential fall would be in each case for the various areas, but have worked out an example in the paper to show how these columns could be employed in giving the increased area required when the length of the conductor would cause the potential fall to be too great.

Perhaps you will permit space for another example. A current of 1,000 amperes is to be conveyed to a distance of 500 yards with a maximum potential fall of 10 volts = 1 volt per 100 yards. Annual cost per electric horse-power works out to £10, and conductor to £200 per ton. The economical area, viz., 1·4 square inch would give a potential fall of 1·68 volt per 100 yards. We must therefore put in a heavier conductor, and the table gives an area of 2·4 square inches for 1,000 amperes to produce the potential fall of 1 volt per 100 yards. I have assumed the whole of the current drawn off at the far end of the conductor.—Yours, &c., W. GEIPEL.

Hull, May 5, 1884.

## THE RECENT THUNDERSTORM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may interest you to hear of a somewhat curious and alarming, though happily harmless, phenomenon in connection with the severe thunderstorm which burst over London yesterday.

During the storm one of our staff who was sitting near the telephone heard a loud crack in the instrument, and, looking up, saw a blaze of light, which shot across the room in the form of a ball of vivid light, and, passing over his head, burst on the other side of him, doing no harm. He was much alarmed, and at once ran into the private office describing what he had seen. We presently rang up the Exchange—after the storm had passed over!—to see if the connections were injured, but everything appeared to be in order. This seems a curious instance of the glow discharge, and shows the danger of using the telephone during a thunderstorm in the immediate vicinity.—Yours, &c.,

LAING, WHARTON, AND DOWN.

London, May 5th, 1884.

[Something of the same nature occurred at my own private residence. One of the servants was frightened at the storm, and my wife, son, and youngest daughter went down into the kitchen. According to the description, the room was at the time of one of the lightning discharges filled with a blaze of blue light; the boy received a shock, which frightened him, and the little girl also complained of a stinging sensation in her leg, and a momentary blindness. The boy professes not to have seen the lightning, only felt the shock.—ED. *E.*]

## RAILWAY AND ELECTRIC APPLIANCE COMPANY (LIMITED).

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the meeting of the shareholders held on the 18th April, as reported in your issue of the 26th ult., I beg to submit the following summary and analysis of the poll taken thereafter.

Colonel Jackson and Mr. Smith did not offer satisfactory evidence that the terms of compromise are beneficial to the shareholders and that their interests and position are not consistent with the interests of the company. These gentlemen employed the tactics of introducing irrelevant matters relating to other companies and other affairs, and made denials as to their personal relationship to the company which are vague and entirely unsupported. Mr. Smith stated that some of the statements contained in the circular and pamphlet issued to the shareholders were not true, but offered no proof which would impeach the evidence to the contrary. The remainder of Mr. Smith's remarks were of a personal character; and I need only refer to them at present and say that my whole connection with this company and the Williams Company to which Mr. Smith refers is open to the closest examination and scrutiny.

The circulars and pamphlet which have been issued to the shareholders were referred to by Colonel Jackson as "extremely amusing documents," but the only single attempt which Colonel Jackson made to reply to the statement submitted was with reference to the balance-sheet.

This balance-sheet he professed to be unable to comprehend, and characterised as a "mass of absurdities;" but time will show whether such is the case.

Colonel Jackson stated that the number of proxies held by the directors was so considerable that they could outvote and checkmate the attempt to govern the affairs of the company in opposition to the course proposed by the directors.

The result of the poll was as follows:—

ORDINARY GENERAL MEETING.

Resolution for adoption of the report.

| | |
|---|---|
| For the resolution | 57,917 |
| Against | 25,216 |
| Majority | 32,701 |

EXTRAORDINARY GENERAL MEETING.

Special resolution.

| | |
|---|---|
| For the resolution | 58,287 |
| Against | 25,116 |
| Majority | 33,171 |

In analysing this poll it will be found that out of the 57,917 shares voted in support of the directors and the terms of compromise 40,450 were fully-paid shares, which the directors in their report informed the shareholders were transferred to Colonel Elliott and Colonel Jackson in trust for the company, and that 11,644 were held by the vendors, promoters, and those specially connected with them, leaving a balance of 5,823 shares. Of this number 3,700 were held by the directors and their personal friends, the remaining 2,123 shares to be accounted for presumably represent independent shares, provided the 1,000 shares of Mr. Arroll are not included in these 2,123. The 25,216 shares voted against the resolution contain 17,500 referred to by Colonel Jackson, leaving a balance of 7,616 shares, in which 4,000 shares of the Maxim-Weston Company are included.

Such facts characterise the terms of compromise, and the value of Colonel Jackson's remarks with reference to the votes he controlled at the meeting can be readily estimated, and a simple examination of these suggestive figures renders further comment unnecessary at present.

Various statements in public print make it appear that at

Digitized by Google

the adjourned meeting for declaring the poll Colonel Elliott said "that the resolution was not carried by the requisite majority, although that was practically of no consequence."

In view of proceedings in accordance with such statements the Court has been moved, and Vice-Chancellor Bacon has granted an interim injunction for the present.—Yours, &c.,

London, May 1st, 1884. JOS. S. WILLIAMS.

## A "B" FOR AN "S."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It must have been an ingenious man who ever thought of any query as to whether a word was "bones" or "stones." I have seen "boot" taken for "soot," "stile" for "Nile," also "Macestoy" for "MacEvoy" but how any one could mistake

· · · — — — — —· · · ·

for

— · · · — — — — —· · · ·

is a puzzle to—Yours, &c.,

A MORSE HAND SINCE 1867.

## A HISTORY OF ELECTRIC TELEGRAPHY TO THE YEAR 1837.

BY J. J. FAHIE, MEMB. SOC. TEL. ENGS. AND ELECS.*

### CHAPTER VII.

(CONCLUDED FROM PAGE 595.)

"The ends of the galvanometer wires are passed onwards to a key-board at the working end of the telegraph. This key-board contains eight keys, a pair being attached to each wire, the one passing a negative, the other a positive electric influence through the line of wire. The needles are so adjusted that the one is effected by the positive, the other by the negative current, so that each wire works a pair of needles.

"Behind the cards at the reading end of the telegraph is a permanent back, with characters upon it, disposed in four columns and nine lines. The two backmost cards have also characters upon them, disposed in two columns and nine lines. There are thus in all eight columns and nine lines, or seventy-two distinct signals. The cards have a variety of openings cut in them for displaying the characters, so arranged that only one character is displayed at a time. The four hinder cards are cut so as to display in succession the eight columns, and the four front ones so as to display eight of the nine lines, also in succession, the uppermost line being seen when the four front cards are at rest.

"Thus when any one of the four hinder cards is touched alone, it displays a character on the first line. The outermost displays the character situated on the extreme left column of the permanent back, and the innermost that situated on the extreme right. When the first and third keys are touched, the characters on the left column of the backmost card are discovered, while the first and fourth display those in the right-hand column. When the second and third keys are touched, those in the left-hand column of the second backmost card are displayed; the second and fourth display those on the right. It will be thus seen how the whole eight columns are displayed. The innermost of the four front cards, corresponding to No. 5 of the keys, when raised alone, uncovers the second line; the next the third, the next the fourth, and the outermost the fifth. When the fifth and seventh keys are touched, the sixth line is displayed; the fifth and eighth display the seventh line. The sixth and seventh keys display the eighth line; the sixth and eighth display the ninth.

"From this explanation it is easy to see how any one of the seventy-two signals can be made to appear.

"The following is the arrangement adopted in the present model:—

| Signs. | Keys. | Signs. | Keys. | Signs. | Keys. |
|---|---|---|---|---|---|
| A | 1 | J | 1·3·6 | S | 1·6 |
| B | 2·7 | K | 1·5 | T | 3·6 |
| C | 4·5 | L | 3·8 | U | 1·3 |
| D | 4·6 | M | 1·8 | V | 4·7 |
| E | 2 | N | 2·8 | W | 1·4 |
| F | 3·7 | O | 4 | X | |
| G | 2·5 | P | 1·7 | Y | 2·5 |
| H | 2·4 | Q | 3·5 | Z | 2·6 |
| I | 3 | R | 4·8 | | |

* The author reserves all rights of translation.

The remaining signals are dedicated to the exhibition of figures, points, arithmetical signs, and combinations of letters; but it is unnecessary to particularise the arrangement. Of course they are all produced by touching either three or four keys together.

"It will be observed that any one of the four front cards may be touched alone without producing any signal. This might be taken advantage of to extend the number of signals to 120, by employing the needles which move the front cards to shift the permanent back."

In the improved model of June 20, 1838, Ponton had so contrived matters as to be able to reduce the number of line wires to four, by the various combinations of which into metallic circuits as in Cooke and Wheatstone's five-needle telegraph, and by using positive and negative currents, he was able to show forty-eight different signals. The work of the electric currents was also reduced to a minimum, slight deviations of the needles being all that was necessary.

Proceeding on the principle that in all correct telegraphing every signal made from one end should be repeated back from the other, he adopted the plan of exhibiting the signals, not in their direct transmission, but on their repetition, and by an arrangement which allowed the signal-indicating apparatus to be worked, not by the needles as before, but by the hand of the receiver in the act of repetition.

The galvanometer needles were eight in number (two in the circuit of each wire), and bore marks corresponding to keys, which, on being depressed, sent positive or negative currents into their respective line wires, and, at the same time, uncovered the letters, figures, or signs with which they were in train. Whenever, therefore, any of the needles were deflected, the receiver had only to depress the corresponding keys, by which act he repeated the signal back to the sending station, and uncovered the letter, figure, or sign which that signal was intended to express.*

The following table shows all these signs and the numbers of the keys which entered into their formation:—

| Signs. | Keys. | Signs. | Keys. | Signs. | Keys. |
|---|---|---|---|---|---|
| A | 1·4 | I | 4·5 | Q | 1·4·7 |
| B | 1·6 | J | 4·7 | R | 1·4·8 |
| C | 1·8 | K | 5·8 | S | 1·6·8 |
| D | 2·3 | L | 6·7 | T | 2·3·5 |
| E | 2·5 | M | 1·3·6 | U | 2·3·6 |
| F | 2·7 | N | 1·3·8 | V | 2·3·7 |
| G | 3·6 | O | 1·4·5 | W | 2·3·8 |
| H | 3·8 | P | 1·4·6 | X | 2·4·5 |
| Y | 2·4·7 | | | Z | 2·5·7 |

| | | | | | |
|---|---|---|---|---|---|
| , | 2·5·8 | 1 | 1·3·5·8 | 8 | 2·3·5·7 |
| ; | 2·6·7 | 2 | 1·3·6·7 | 9 | 2·3·5·8 |
| . | 3·5·8 | 3 | 1·3·6·8 | 0 | 2·3·6·7 |
| & | 3·6·7 | 4 | 1·4·5·7 | + | 2·3·6·8 |
| Sig. | 3·6·8 | 5 | 1·4·5·8 | − | 2·4·5·7 |
| E R | 4·5·7 | 6 | 1·4·6·7 | × | 2·4·5·8 |
| R E | 4·5·8 | 7 | 1·4·6·8 | ÷ | 2·4·6·7 |
| E N D | 4·6·7 | | | | |

Ponton added an alarum, which was a very simple affair, and recalls a somewhat similar one of Edward Davy, previously described. An extra galvanometer was placed in the circuit of one of the line wires, and across its needle was placed a fine platinum wire, which normally rested against a lucifer or other quick match. Above the match was a thread holding back the hammer of a bell or the detent of an alarum. To sound the alarum the proper keys were held down for a few seconds, the needle of the galvanometer was deflected and carried the piece of platinum wire into the flame of a spirit lamp; then on reversing the direction of the current in the line the red-hot wire was suddenly brought in contact with the match, which, igniting, burnt the string above it and so released the hammer of the bell or the detent of the alarum.†

On the report of a committee, an honorary silver medal was awarded, in December, 1838, to Mr. Ponton, "for the ingenuity of his plans, as manifested in the working model which had been presented to the society."

* With a little practice this would have been found to be a work of supererogation, for the operators would soon have come to know the values of the deflections, without the need of reproducing them in black and white. Again, it would soon have been found that four galvanometers would suffice; and thus the system would resolve itself into a four-needle telegraph.

† A supply of matches and strings would of course be necessary. In the ordinary course of signalling, the platinum wire would often be in the flame of the lamp, but never sufficiently long to be heated to the point of igniting the match; so that, as Ponton points out, there would be small risk of unseasonable alarums. Ponton also suggested an alarum by the direct action of a rather heavy galvanometer needle striking against a bell when deflected by the current.

## "ELECTRIC LIGHTING IN OUR HOMES."

Under the above title, we believe, some lectures have been delivered, and some books issued from the Press, designed to convince the public that electric lighting for domestic use is both safe and economical. The public apparently have received the latter of these assurances with reserve, not to say scepticism. It is, perhaps, unfortunate that, in one instance at least, advocacy of this system of lighting has been associated with the management or promotion of systems which had notoriously failed; and it was manifestly inopportune to appeal to the public just at a time when its confidence had been shaken by the financial collapse of almost every electric lighting company on the market. Some independent testimony will have to be forthcoming before a feeling of hopefulness can be re-established in the public mind, and perhaps the last persons in the world to inspire it are the people whose names are connected with the speculation, panic, and insolvency of the past two years. We are glad to notice, therefore, that such independent testimony is rapidly accumulating, at all events with respect to indoor electric lighting; and we now confidently look forward to its development on a sound basis, though the pace may not be so rapid as some people expected in the first instance.

The kind of testimony to which we refer is that mainly of persons who have tried the electric light in their homes and pronounce it a success. The columns of *The Times* newspaper have furnished abundance of evidence on this point, and several letters recently published by ourselves are equally encouraging. Besides this we have made known from time to time various private installations on the premises of persons who do not write to the newspapers, but whose continued use of the electric light proves their entire satisfaction with it. Some of these installations are on a large scale, that is to say, are for the lighting of extensive premises covered by the designation "country residence;" others are for the narrower requirements of a "town house." In some the power is obtained direct from a gas engine; in others it is supplemented or superseded by secondary batteries; whilst in two or three instances which are known to us turbines have been employed with extremely satisfactory results. In the last-named cases the working expenses are probably least of any; but in none is the cost complained of as being excessive or prohibitory. Compared with the cost of gas under similar circumstances—gas indeed being often unobtainable except in the immediate vicinity of towns—the price of electric lighting is not much higher, and, compared with other illuminants (exclusive of mineral oils, which are very cheap, but dangerous and malodorous) electricity is, light for light, the least expensive. We say light for light, because in domestic lighting of the kind we refer to there is no waste of light as with arc lighting. What the owner wants is more light than he has been able to obtain with the ordinary means at his disposal, and if he can get the extra light he is willing to pay for it. This is an important consideration in recommending electric lighting for country mansions and similar establishments where gas is either of poor quality or unobtainable, or where its use is objected to by the proprietor on any grounds whatever. He would willingly pay for a better light throughout the whole establishment, and a light giving less trouble to maintain, if money would purchase it; therefore the true comparison of cost is with the local light available increased to the power of the electric light actually substituted. In the majority of cases we say the comparison will be favourable to electricity.

Even when this is not the case there are other obvious considerations which will certainly weigh with occupants of houses containing valuable pictures, books, furniture, and decorative fixtures. The absence of gas deprives these accessories of half their use and beauty during the winter months, whilst on the other hand the employment of gas necessitates periodical cleaning, frequent renovation, and ends in more or less rapid destruction. As a fact, gas has gone out of fashion with the wealthier classes to a much greater extent even in our great cities than is generally supposed, the employment of candles and the costlier oils being preferred on artistic grounds, if on no other. Here also, therefore, there is a good field for electric lighting, not because it is cheaper than gas, but because it is as cheap as the illuminants actually used, is much safer, is a far better light, and gives infinitely less trouble to the servants. Add to this that it is free from the least objection on the score of dirtiness or unwholesomeness, and it will be seen that we have a system of lighting which in proper hands may be recommended and pushed forward entirely on its merits, with excellent prospect of a good market. It is significant also to notice that the installations to which we have confined our observations are dissociated from speculation and company-mongering. They have been conducted on ordinary business principles, and the results, so far as we can gather, have been not less satisfactory to the vendor than to the customer. We have always maintained that if outdoor lighting had been carried out on that principle it would have succeeded.

When these isolated installations become more numerous, especially in the residential districts of our cities, there will arise the possibility of combining the operations and greatly reducing the cost. At present each one has its separate turbine, gas engine, or secondary batteries, and of course the expense is greater than it ought to be, or will be when the system becomes more general. The use of a gas engine on the premises is not always desirable or even practicable; combination would allow of the withdrawal of the engine to a greater distance and of its being attended to independently of the users. But it is to secondary batteries that we should look for the greatest improvement of all. At present they are under a cloud; but the immense service they would render just now is so generally appreciated that we confidently expect the need will not long remain unsatisfied. The problem of domestic lighting on any extended scale does, in fact, depend for its solution upon the construction of some battery at once durable, portable, and trustworthy. Its cheapness is not a matter of first importance; its efficiency is.

## LEGAL.

### THE CENTRAL NEWS COMPANY v. THE EASTERN TELEGRAPH COMPANY AND OTHERS.

[In the Queen's Bench, before Lord COLERIDGE and a Special Jury.]

This case, which was before the Court from April 26 to May 7, had become the most important of telegraphic cases in recent years; and, pursuing the policy which we have held during the existence of this paper, viz., the publication of all matters that aid in the continuity of the history of telegraphic, telephonic, and electric light enterprise, we must endeavour to give a fair and impartial account of the trial. Our description of the proceedings can only be in abstract, but we hope the abstract will present a faithful record of the trial. This abstract, together with the summing up of the Lord Chief Justice—which we give verbatim—will enable any reader to satisfy himself as to the facts of the case.

Mr. Murphy, Q.C., Mr. A. Sullivan, and Mr. Dickens represented the Plaintiffs; the Attorney-General, Mr. C. Russell, Q.C., and Mr. Moulton represented the Defendants, the Eastern Telegraph Company, Sir James Anderson, and Mr. Benjamin Smith; the Solicitor-General, Mr. Bompas, Q.C., and Mr. Jeune, represented the Exchange Company.

Mr. MURPHY, Q.C., in a very eloquent and powerful speech, opened the case for the Plaintiffs. He dwelt very strongly upon the moral as well as the legal points, and briefly put the case thus:—The case was most important, because the Defendants were charged with about as gross a breach of trust as could possibly be committed by persons in the positions in which they were severally placed. The Plaintiffs employed the Eastern Telegraph Company to transmit telegraphic messages. Sir James Anderson was managing director of the Eastern Company, and at that time chairman of the Exchange Telegraph Company, the latter being a rival to the Central News. It was suggested that Sir James Anderson authorised or connived at the tampering with telegrams sent to the Central News, and the information thus obtained was sent to the Exchange Company. Two cases were specially mentioned. Of one Mr. Murphy spoke as follows: -

"It was an utterly trivial incident, but unhappily the suspicions of the Central News had been already aroused as to the conduct of the Telegraph Company, and consequently when they received this message, the portion of it which refers to the burial of the body in the tomb of Sheikh Ali was omitted from the publication that they sent to their subscribers. No living being save those connected with the Eastern Telegraph Company could either know that that message was sent, or that the information came back about the burial of the body in the tomb of Sheikh Ali, and judge of their surprise when, on the same afternoon that they had received that telegram, there appeared in the Exchange Company's telegram the following:—'Alexandria, Tuesday, 1 p.m., statement in the papers that the body,' &c. The Exchange Company had no correspondent who sent them that news, and the reference to Shiekh Ali's tomb could only have been known by the officials of the Eastern Telegraph Company, and upon seeing in the Exchange Telegraph Company's papers the publication of that which obviously had been copied from theirs, the representative of the Plaintiffs called upon the representative of the Eastern Telegraph Company and directed his attention to the matter, upon which he said, 'Oh, the matter is very simple, it is the old story, your correspondent has been forestalled by our correspondent, you are very well represented out there, but of course other people are also; *The Times*, *Daily News*, the Exchange Company have most excellent correspondents, and you must not be surprised at this little coincidence.'"

The other case turned out to be the sole important one, and referred to a telegram sent announcing the victory of Tel-el-Kebir. The Plaintiffs had two correspondents with the army—Mr. Burleigh and Mr. Cunnington. On the eve of the battle Mr. Burleigh arranged to go to the front, leaving Mr. Cunnington with instructions to stop by the telegraph tent, watch for Mr. Burleigh's arrival, and on sighting him get the wire. Mr. Burleigh saw the commencement of the battle, went with the troops inside the trenches, coolly and calmly watched the progress of the fight, saw victory assured, estimated losses, guns captured, prisoners taken, and then galloped back to Kassassin. He got possession of the wires, and sent off at 6:10 a telegram of 922 words. The first few lines of this telegram contained the information—40 guns taken, 200 killed, and so on. In London, at 9:30, the Exchange Company published a short message, which also stated that 40 guns were taken, together with other coincident words. The Burleigh message came first into the hands of the Defendant Company at Port Said at 9 o'clock. It was now suggested that the message sent from Port Said to Alexandria was seen by Mr. B. Smith on board the "Chiltern," and that Mr. Smith, having read the first portion of the message, wrote out a service message containing the pith of the information, stopped the sending of the Burleigh message while the service message was sent on. With regard to the information that found its way to the Exchange Company, Mr. Murphy said:—

"It will turn out that there was received at or about 11 o'clock, as the witness said, speaking from memory, a message from Sir Charles Wilson to Sir Edward Malet, which he properly says was the first message that brought any news to Alexandria. That message was not made public. That message was copied from Mr. Burleigh's telegram as I shall demonstrate, the message was copied innocently by Sir Charles Wilson from my telegram, it was copied long after the Burleigh telegram was at Port Said. It was sent to Sir Edward Malet, and it was forwarded within a week or two to Lord Granville. It has been found by us, within the last day or two only I regret to say, in one of the Blue Books, and here it is. 'Sir Edward Malet to Earl Granville, 'Wilson telegraphs from Ismailia at nine o'clock,' my telegram having gone on long before, 'Tel-el-Kebir carried this morning in twenty minutes, forty guns have been taken as well as a large number of prisoners. The cavalry are in pursuit of Arabi's force, which appears to be quite broken up.' That is the very copy which found its way into the Exchange. Now, if I have succeeded in showing, as I hope I have, that the Exchange telegram was taken from the Burleigh message, it does not require any further argument to show you that this was taken also, and I believe what occurred was this. Sir Charles Wilson came in at 9 o'clock to Ismailia, found the telegram from Burleigh lying on the table, knew it had gone on three hours before from Ismailia, and was probably published at the time, and I understand did that which was a wrong thing to do, no doubt, but still nobody could complain under the circumstances of his doing it, he sent it direct to Sir Edward Malet, who was impressed with the importance of it, and knowing that was the first news instantly sent it to Lord Granville. When did he send it to Lord Granville? If his lordship will look at the hours on this message the matter will become much more serious than these Defendants think. Sir Charles Wilson telegraphs at 9 o'clock, Sir Edward Malet telegraphs to Lord Granville at a quarter past 11. When did Benjamin Smith send the service message to Sir James Anderson? At 10 minutes past 11. He stopped the message from Sir E. Malet to Lord Granville in order to send it on to his friend Sir James Anderson, not merely betraying us, but it looks as though he betrayed Sir E. Malet and the Government.

After a lengthy reference to times of receipt, transmission, delay, &c., the evidence to be brought forward in the person of a former clerk of the Eastern Company named Biancardi was discussed. This Biancardi told how he was on board the "Chiltern" acting as check clerk when the Burleigh message began to arrive about 9 a.m. Between the 300th and 400th word Mr. Smith came in, read the message, wrote a service message from it, and sent on the service message, stopping the transmission of the Burleigh message, because the service message had to be sent on the same line. Mr. Smith then took away the sheets containing Burleigh's partly received message, and was away about three-quarters of an hour.

Mr. JOHN MOORE, a director, acting manager, and editor of the "Central News," was called, and testified as to the business of the Company, the special correspondents sent out, the arrival of the message, the communications with the Eastern Company on the publication of the Exchange telegram, and in cross-examination admitted that on some occasions the Eastern Company had sent information gratuitously for public use, and that Mr. Burleigh had spoken about the original service message being given by a clerk of the Eastern Company.

Mr. HOWARD CUNNINGTON testified as to his position as correspondent, his arrangement with Mr. Burleigh on the eve of the battle, his sending of pre-arranged messages at an earlier hour than the one in dispute, and as to messages of other correspondents.

ROBERT TUTIN, Colonel C. E. WEBBER, THOMAS TERIN, Corporal JOHN SULLIVAN, PATRICK FRANCIS LARKIN, JAMES OAKES, and WILLIAM CHARLES HAYZY, all connected with the military telegraphs, testified as to what took place on the morning of September 13, and as to the messages sent, the time and order in which they were sent, &c.

Mr. BENNET BURLEIGH gave evidence as to his position as correspondent, his arrangements with Mr. Cunnington on the night of September 12, how he saw the battle, estimated the results, hastened back, and sent his telegram of 922 words.

Mr. W. SAUNDERSON testified as to the manner in which the business of the Central News is conducted.

ANNETTO BIANCARDI (the case was practically opened upon this witness's evidence) testified that on the night of September 12 he slept on board the "Chiltern," and on the morning of the 13th was on duty as check clerk; that the instrument room was small, and that Mr. Brown was at the instrument. That only one wire was in use to Malta, that he remembered the Burleigh message, that Mr. Smith came in during its receipt, read the part received, wrote and sent off a service message, stopping the transmission of the Burleigh message to Malta by so doing. In his cross-examination by Mr. Russell the witness was most emphatic as to his story. He described the whole scene minutely, and maintained that the message was delayed from forty minutes to an hour in transmission. The cross-examination, however, went on to show that the cables were removed from the "Chiltern" before 7 o'clock in the morning, and that clerks and instruments were transferred to the "John Pender," that during a portion of the time before the "John Pender" was fully connected part of the work was through the town office, and that as a matter of fact no such message could have been received or transmitted on the "Chiltern" after 6 o'clock that morning, while the time the witness swore to was after 9 o'clock.

#### THE DEFENCE.

It is to be regretted that the want of space prevents us giving the opening and closing speeches of the Attorney-General. These speeches went to the root of the matter. The evidence for the defence was given by Mr. A. R. Rampler, superintendent at the office, Port Said; Mr. C. Barret, in the employ of the Eastern Company at Port Said, as counter clerk; Mr. G. U. Scott, also in the employ of the Eastern Telegraph Company, as instrument clerk; Sir C. Wilson, Lieut.-Colonel Royal Engineers (who appeared at the request of the Lord Chief Justice); Capt. W. Goodsall, of the "Chiltern;" Mr. C. H. Phillips, electrical engineer, in the employ of the Eastern Telegraph Company; Messrs. J. F. Jeremy, E. P. Austice, F. Brown, F. S. Gruchy, F. J. George, R. C. Reynell, A. Barcio, and P. Burrell, in the employ of the Eastern Telegraph Company; Mr. B. Smith, manager to the Eastern Telegraph Company in Egypt; Sir James Anderson and his son Mr. Kenneth Anderson. The evidence given was to prove that from the time the Burleigh message came into the hands of the officials of the Defendant Company neither delay nor tampering took place. That it was in fact sent on as fast as possible. The officials in the employ of the Company were called in the order in which they received the message. Thus from Mr. Ramplin in the employ of the Egyptian Government it passed to Mr. Barret of the Eastern Telegraph Company, and so the message was traced till its transmission from Malta.

Digitized by Google

Sir CHARLES WILSON testified that the information upon which he framed his message to Sir Edward Malet was obtained in the first place from a servant, and corroborated by members of the staff, amongst whom the facts seemed generally known.

It was admitted that Mr. Smith telegraphed to the managing director—excepting three words, which were erased to shorten the message—the message of Sir C. Wilson, *verbatim et literatim*, and he denied emphatically that he had taken any information from Mr. Burleigh's message. The examination and cross-examination of Sir James Anderson dealt mostly with what we might term the personal equation, and is sufficiently referred to in the summing up of the Lord Chief Justice, which was in the following terms:—

SUMMING UP.

The LORD CHIEF JUSTICE: Gentlemen of the jury, this case has occupied more than a week in trial, and at last, as it seems to me, the question for you and for me is narrowed to an extremely short and an extremely simple one. It will nevertheless be proper that I should, with some little fulness, express to you the general views that I entertain upon the various topics that have been put before you. Most of those topics, I should say nine-tenths of those topics on one side, and I may say very possibly not a little on both, have been addressed—with a good deal of boldness—to your prejudices rather than your reason; and you have been invited to give a verdict in this case, not as far as I have been able to ascertain upon any legal grounds that have been put before you which can be maintained, but upon eloquent forcible denunciations of particular persons, and particular acts connected with those transactions, and mainly, as far as I can make out from the constant reiteration of the sum, because the Plaintiffs paid £92 for a message which somebody else anticipated, which may be a matter of regret to us; but unless there should be found upon examination something like a sound legal principle upon which the Plaintiffs can maintain an action against the Defendants, if they had paid ten times £92 and had been ten times anticipated your verdict ought not to be for them. I am almost ashamed to mention it, but after the eloquent and forcible and slightly exaggerated language (if I may express an opinion) in which you have been addressed, it is necessary to say so, because the learned counsel seems to think that those are topics of prejudice which, addressed to you as judges (because judges you are, and sworn judges you are) are topics which may perhaps influence your conscientious determination of the questions of fact. I should otherwise be almost ashamed to address you upon them. It will, however, be necessary for me to place before you what my view of the law is, which, right or wrong, is clear enough, and will be expressed as far as my powers go in language that I will try to make intelligible. I think I know enough of you to believe that whatever you may think of it, whatever you may think of the propriety of it—I mean as to whether it is a just or an unjust law, or whether in the particular case it does or does not work hardship—you, as jurors, with whom I have spent a great many more years than it is now pleasant to recollect, I am fully persuaded will do what you think is your duty according to the law, and according to the law that for the present the presiding judge lays down to you. One is reminded constantly that one is a fallible mortal, and certainly, as one has occasion to say elsewhere, the judges are not indisposed to remind one another that fallible they are; but still, for the purposes of to-day I am for you and for the purposes of this trial that infallible external standard which some of our brethren of another religion delight to find in the head of their form of Christianity, and for the purposes of the trial and to the jury the judge for the day must be taken to be right. Of course if he is shown to be wrong afterwards that is another matter altogether.

Now I put out of sight to begin with, because it will tend to clearness, all questions of every sort, kind, and description relating to the Exchange Company. There is by the concession of both parties to this dispute, by the concession of the Solicitor-General and by the admission of Mr. Murphy, no question of fact for you in relation to the Exchange Company. If you think one way or the other upon another matter, which of course I shall carefully submit to you, then there arises a legal question as to whether the Exchange Company will or will not be bound; and the only question I shall ask you in that regard is—supposing that it should turn out that there is a legal liability on the Exchange Company—to what extent do you think that Company should meet that liability in damages? That is the only question I shall leave to you in reference to the Exchange Company. Mr. Murphy has not suggested that the Exchange Company, as a Company, has done anything in itself wrong. He has not suggested that the managers of that Company, getting this piece of information from an accredited source, were not morally justified in making use of it. They did not know where it came from, and he does not say they were not justified in making use of it. Whether they were legally justified is another matter, but on the question whether they did anything wrong he does not seem to say they did. The Solicitor-General has not put their case before you, because no attack personally, so to speak, has been made on the Exchange Company, and the facts in relation to the Exchange Company are not in dispute. The Plaintiffs in this action, therefore, being the Central News, and the Defendants being the Eastern Telegraph Company, Sir James Anderson, Mr. Benjamin Smith, and the Exchange Company, for the rest of my summing up I pass away altogether from the Exchange Company, and leave no question to you except the hypothetical question of damages in case any legal liability should be capable of being sustained against them. I will only say my own present impression is that no such legal liability can be maintained, but there again I may be wrong. At any rate it does not depend on any question of fact or anything that I can leave to your determination except the question of damages. That leaves, however, the great question in the case—the question which has been disputed with great vehemence on both sides in this matter—whether the Eastern Telegraph Company and Sir James Anderson and Mr. Benjamin Smith, or any of them, are liable to the Plaintiffs for any wrongful act which they have done towards them. The paper is only material as showing how they propose to shape their case in the first instance, because now we are not bound, happily, by the statements upon paper; because if there is any real difference between the statements on paper and the proof in fact, the paper is always amended to meet the proof, and therefore the use of the paper is to show how the case originally in the minds of the legal persons who framed it appeared proper to be sustained; but both by looking at the paper and by listening to the argument it seems to me that there can be but two and two grounds only on which this action can be sustained against the Defendants, or any of them; and by the Defendants, or any of them, as you understand, I mean now the Eastern Telegraph Company, Sir James Anderson and Mr. Benjamin Smith.

Now, it is put in two ways. First of all, it is said, as I understand the contention of Mr. Murphy, that they interfered with some right of property which the Plaintiffs had in their message transmitted to them by Mr. Burleigh. I express myself in that vague way for a reason you will see presently. He has put it in a way in which I myself doubt whether it can be sustained, but there is a way in which I am of opinion that upon your coming to a certain conclusion on certain facts it may be sustained. First of all, it is said that the Defendant Company have interfered with the rights of property of some kind or another which the Plaintiff Company had in the message which Burleigh transmitted to them. Secondly, it is said that even if such rights of property, strictly speaking, did not exist, still there was a conspiracy—an unlawful agreement or combination—on the part of the Telegraph Company, of Sir James Anderson, and of Mr. Benjamin Smith, or on the part of Sir James Anderson and Mr. Benjamin Smith, for two people are enough to make a conspiracy; and even if you thought the Telegraph Company itself had nothing to do with it, still you might be of opinion that Mr. Smith and Sir James Anderson conspired, and it is put as a qualification that those two gentlemen conspired, that is, unlawfully and wrongfully agreed together to defraud the Plaintiff Company of some benefit or advantage to which they had a right. Whether they succeeded in doing it or not is immaterial, because as has very often been pointed out—and the law is so—the gist, as it is called, of the conspiracy lies in the unlawful and wrongful combination in the minds of the parties to it. A conspiracy may be defeated, a conspiracy may fail, but it is none the less a conspiracy and none the less indictable or actionable; because what the law holds to be indictable or actionable is not the consequence of the conspiracy but the conspiracy itself—the agreeing together of two minds to effect an unlawful object by unlawful means, or a lawful object by unlawful means. Those are the two matters on which this case, as I understand it, depends. Stripped of a good deal of that which I cannot help saying (and I hope Mr. Murphy, though he is not here, will forgive me) has been, rather audaciously I should say, addressed to your prejudice than your reason—stripped from those considerations, those are the two points to which it is very important you should give your attention.

Now, gentlemen, I will take the last point of conspiracy first, because that is much the more important, and there is the less evidence upon it. But before I address you on that particular point it seems to me fair and right that I should tell you how the matter strikes me, and how much force, if any, there appears to me to be in some of the observations which have been powerfully and rhetorically addressed to you in the course of this case. I do not wish to blame anybody, because it may be the inevitable result of circumstances over which neither side had control; but I must say that when you come to consider, as I shall do with you presently, what is the real question here, it is a monstrous thing that you and I should have eight or nine days taken up with the discussion of a point so small, and admitting of being put very plainly and very simply. I am by no means saying there are not two sides to that point, but it is a point which might have been very easily and simply put—and, indeed, Mr. Murphy himself did not deny in his able reply yesterday that that was so. He threw the blame upon the Defendants, and said it was the Defendants' fault entirely that they had not shown their hand, what their real defence was, and that therefore he had consumed a great deal of time which he quite admitted had been unnecessarily consumed. A great deal of the defence which they have put forward to a considerable portion of his attack he admits is conclusive, and he withdraws that part of the case from your consideration; but he says if he had known what their answer was, if he had seen their papers and been aware of what they could prove, he would not have made the sort of attack he did. I do not mean by that that he would not have said there was a strong case against the individuals, but he would not have shaped his attack in the form in which he did shape it. As I say, I do not want to blame anybody, but I must say I do not quite accept that view which has been so ably put forward. I do not at all deny, and no fair man can deny, that a Company such as the Central News, after having paid £92 (we shall never forget that £92 as long as we live I am sure) for a message, finding itself anticipated, was annoyed. It was an irritating thing, it was a thing that was annoying, more particularly as the message had been got, I quite agree, in a very daring and brilliant way, and had been telegraphed in that sort of rapid, graphic style which I am sure we humble, steady, plodding people in a court of law greatly envy, and which in the possession of many of these people—these newspaper correspondents—is an enviable power, and one to be very much admired in its proper use. I do not wonder at all the Central News were annoyed, and I do not wonder that Mr. Burleigh was annoyed. He had telegraphed this at length, and with great eloquence, and the substance of his news was anticipated. I do not wonder either at all—it is a very fair matter for observation—that the Central News, finding this anticipation, and their news coming a quarter of an hour or twenty minutes, or whatever time it was, after the other—I really forget exactly what time, but it does not affect it much whether it was one hour or

Digitized by Google

twenty minutes—that they were anticipated, were not first in the field, I do not very much wonder that they should cast about for some explanation of it, and finding Sir James Anderson, the managing director of the Eastern Telegraph Company and the chairman of the Exchange Company, chairman of the Company which had anticipated them, the Central News—I do not much wonder at their saying, in the first instance, "There you have it," and "No doubt our message got tapped, and Sir James Anderson got knowledge of it." This is a very unfair result, and it comes from this equivocal position which Sir James Anderson occupies. I do not wish at all to discuss, any more than I am bound to say in fairness Sir James Anderson wished to discuss, that the position that he had occupied from the time the Exchange Company became a general purveyor of electric news, that his position as managing director of the transmitter of news and chairman of the collector and distributor of news was an inconsistent position, and might lead, as it has led, to damaging, or, at any rate, apparently damaging, attacks upon him, and that it might give rise to suspicion in the minds of persons, not unfair or particularly acute to find fault, but that it might be honestly and justly suspected. As I say, I must do Sir James Anderson the justice to say that he seems to have felt that himself, and the Exchange Company having been a Company for disseminating Stock Exchange news only up to a certain time (the exact dates here are not material, because they are all long before this particular transaction) some time early in 1882—somewhere about April or May, in consequence of negotiations which had taken place with the MacMahon Company and some other company, the Exchange Company, having been purely a Stock Exchange affair, turned into a general purveyor of news and a general collector and distributer of news. It is all very well to sneer at Sir James Anderson and call him hard names, but there is no proof that I can see, and there was no cross-examination even addressed to the fact. But somewhere, however, soon after this, about May or June, a long time before any of these transactions are suggested to have happened, Sir James Anderson himself said, "I must resign; I cannot go on; I am mixed up heavily, and deeply mixed up with the Eastern telegraph system, I am the managing director of this great system of telegraph companies, or if not managing director I am interested in the direction of a number of companies more or less connected with the Eastern Telegraph Company. I cannot any longer continue conscientiously in the position of a receiver and distributer of news from my own Company; it will excite suspicion, suspicion which I want to get rid of, and ought to get rid of." One can easily understand if Sir James Anderson had been a conductor of negotiations, if he was, as it seems he was, the leading spirit to a great extent of a great many varieties of these Telegraph Companies—one can very readily understand that the Exchange Company were not anxious to lose his services as chairman. Any one of you who have been members of companies very well know that if you have got a good chairman, and a chairman that is useful to you, you submit to a great deal and go through a great deal of trouble to retain him, because the chairman is always a most important person, and if he does his work well the company do not like to part with him. Therefore in the first moment, though Sir James Anderson said "I must resign," he did not resign, and the thing was tided over for weeks and even for months, which is only what you would expect in the natural state of things. But he says he was always pressing it, and in September, just about the time when this happened, he ceased practically to be chairman of the Company. He says not in consequence of this, though that does not seem to me to make much difference as far as his character is concerned, because I should have thought it quite as likely, without the least reflection on Sir James Anderson, that when this thing happened, he might very reasonably say—"Now this is the very thing that I knew would happen, this is certain to give offence and to give rise to suspicion, and it is high time I was gone," and he showed his sincerity by never attending, except for the purpose of giving information, any meeting of the Exchange Company after the 26th of September. All this happpened on the 13th, and then on the 26th of September Sir James Anderson practically ceased to be chairman of the Company. Therefore if this was his act, or if he had anything to do with it, this was about the last act Sir James Anderson was concerned with, or had anything to do with as the chairman of the Exchange Company. I do not forget that he was in Scotland, but I assume for the present purpose that he was in some way answerable for what was done in his absence by the two companies—the Eastern Telegraph Company on the one hand and the Exchange Company on the other. I am not saying that there was not, or that there might not have been, something to justify the suspicion of the Central News. I am very far from saying that Sir James Anderson's position was not one which, as he himself felt, the sooner he got rid of the better, and although I do not in the least think there is any fair ground for complaint, nor do I know that the Plaintiffs have complained; but a certain amount of suspicion was attached to the fact that somehow or other from the service message—they did not find that out at the time—but in some way or other the Company of which the managing director of the Eastern Telegraph was chairman had anticipated them in this important matter. I cannot help thinking that the language in which all this has been presented to you is extravagantly exaggerated. But that is entirely for you. You are better judges of it a great deal than I. I suppose one gets old and careless about these things, but I should have thought the immensely powerful epithets that have been heaped up upon this gentleman's conduct, under which, as Mr. Murphy said, his own powers of language staggered and were unequal to describe the enormity of the clouds which these people had brought on themselves—I should have thought, considering there are such things as capital offences, and gross frauds, and other things, which are worthy of those strong expressions, that it was a little overdoing the thing. That is merely a matter of taste and opinion. Mr. Murphy, in the zeal of his advocacy, said just now that language failed him, that there were no words at his command that could express the detestation and horror that he had of this misconduct; but I cannot help thinking that, even putting it at the very worst, that is a little strong. I dare say that I myself, when I was at the Bar, did the same, and I have great fellow feeling for a man who gets into the tempest of oratory and is carried away. Some people are said to be masters of language when language masters them, and there is such a thing as a man being carried off his legs by the impetuosity of his own eloquence; but I do think this matter has been a good deal over painted, and a good deal too strong language used about it. And I will tell you why. There has been no attempt to prove that this was an habitual thing. A good deal has been said about it, but there has been no attempt to prove it. The only definite charge, as far as I remember, was in the evidence of Colbourne and Webber, and was that they had been told to expedite the messages for Diocles, or that there had been stuck up in the various offices in Egypt—Alexandria, Cairo, and elsewhere—something to the effect of expediting Diocles. Expedite was the word about which they were perfectly certain. It is said by Mr. Murphy that that has not been adverted to. Mr. Murphy is certainly mistaken in that, because half-a-dozen witnesses at least, and indeed more than that, I should think a dozen witnesses, have been called—clerks, managers, and people in different positions in the Defendant Company's offices, and they have said that there was no such thing, that they never said it, that they never heard of it, that they never had any such orders given them, that nothing of the kind ever happened, and the only thing, to the best of their belief or knowledge, in which Diocles, the Exchange Company as we know, was ever mixed up, or anything said about it, was that in regard to Diocles, as in regard to *The Times*, the *Standard*, the *Daily Telegraph*, the *Daily News*, and a number of other perfectly respectable and solvent people in England, instead of the messages being paid for over the counter as private people were made to pay in Egypt, they were told, "You may take those messages, charge them to the London correspondents, and the London correspondents will pay us for them." There was the same kind of notice given in respect to the Exchange News, and they say the same had been done for the Central News. The order was put in with regard to the Central News, and they say there was the same thing with regard to the *Standard* and other people, and it does not seem to be disputed that, "R. & P. Receiver to pay," had been put in respect of many of those persons, and among those persons was Diocles. Then it was said, "But you got him a correspondent. You detached one of your clerks to be one of his correspondents. That was a most suspicious circumstance, and you showed that you were furthering him because one of your clerks was told off to be the correspondent of the Exchange News." It turned out to be that that was so, but, and this is not disputed, it was only in company with, I think, *The Times*—certainly with regard to the *Daily Telegraph*, and certainly with regard to Reuter, and I think with regard to one or two other people. So true it is that in the stress of work at Alexandria, after the bombardment of the forts, and when there was a great deal, no doubt, of excitement, and when correspondents were very few and far between I expect—people who could be trusted—the Exchange Company, a great and flourishing Company, with a number of clerks there, was asked to supply, and did supply, a correspondent to a variety of London papers—the London papers and London firms who wanted correspondents. That is undoubtedly true, but when the facts come to be known, see how little there is in what you have to deal with, how very little there is to justify the sort of language, and the sort of opening, and, indeed, the sort of reply that you have heard on the part of the Plaintiffs. There may have been—it is for you, and I carefully leave that for consideration separately (I do not say there was not at present)—there may have been something done in this particular case which gives the Plaintiffs a cause of action. That is quite a matter fit for your consideration, but it does not tend to the fair consideration of that question to bring forward a number of charges, most of which are either disproved or are, when they are found to be hopeless, given up with an air—well, no doubt, Mr. Murphy the moment he finds a thing will not do he says so, but one or two of the main points of this case, as you will say, have been in truth completely given up and admitted to be matters on which he can no longer rely, and though very many of those cases he has like a man withdrawn, and says he no longer puts them to you as points on which he can ask your verdict, he nevertheless ingeniously (I cannot help pointing out to you that he does so) avails himself of the cloud of prejudice which these abandoned grounds of attack have raised in the making of the attack, and finishes his reply very much in the same tone in which he began his opening, when there was a whole number of these things which he then believed in, and which he is now obliged to admit from the force of circumstances he can no longer put before you as being worthy of your credit in any degree.

Now, I must say that there is really nothing at all to justify the general attack, as far as I can see, that has been made upon the Defendants in this case. One would like to have known—if Mr. Murphy had thought it would have told in his favour certainly he was not the man to have omitted it—to what extent these Plaintiffs and these Defendants had done business together; how many messages perfectly properly had been sent along their wire; how much money had passed from one to the other without any complaint whatever. I do not forget the sheikh's tomb telegram, and I will come to that in a moment. How many complaints prior to this had ever been made? What suggestion could Mr. Murphy make, or did Mr. Murphy make, except in general language, that in this case the Defendants had been guilty of the conduct which he says the English language is too weak to enable him to characterise as it deserves? If they have been constantly in the habit of taking from messages of the Central News valuable information and communicating it either to persons in whom they had an interest, or even to persons in whom they had not an interest, in fraud and wrong of the Central News, I will not say that the English language is not strong

Digitized by Google

enough to describe it. My command of it is very limited, and I do not pretend to say I should be able to describe it with the epithets it deserves, because I should quite agree it deserves very strong language; but there is no pretence that I can see in this case for any such charge at all. Mr. Murphy might fairly say in the first instance, "But you kept all the papers; we had not the opportunity of investigation." Be it so. Upon that a word presently; but Mr. Murphy had all last week, Mr. Murphy had the whole of Monday—for we did not sit here on Monday, though I do not suppose we actually took a holiday. There was the whole of Monday. I suppose lawyers never do work on Sunday, or else I was going to say there was the whole of Sunday; I will not, however, make a suggestion which is improper. Besides that there were the evenings, for we have been rising every day—partly for my duties elsewhere, and partly because counsel get tired about that hour—at four o'clock, and although you, gentlemen, have other business to do, counsel have only these things to attend to. They have had a very great number of papers—all the papers that they have asked for—in fact, they have had piles of papers. They have had, as I know, the most intelligent counsel, and very intelligent attorneys; and where, out of all this mass of papers, has anything been picked? They have had the information; why do not they use it? If they can show that the Defendants were habitually abstracting their news, and habitually misconducting themselves, it is most relevant to their case; if they have the materials to prove it, why do they not prove it? There has been no attempt of the sort except in one case. There was an attempt to make it out in one case, and just see what there is in that one case. You will not forget what Mr. Murphy said upon his instructions—every one in the position of counsel must act upon his instructions—about the sheikh's tomb. It was not so important, but he opened it as a specimen of the actual *mala fides* of the Defendants. Said he "It was just the sheikh's tomb over again," and he produced an impression, at least he did on me certainly. I am not ashamed to say I was exceedingly impressed by the opening of Mr. Murphy; I thought it was a strong case requiring a strong answer, and I was very much impressed with the fact of the sheikh's tomb, as well as the other matter. It did not bear on the particular matter in hand it is true, but as an indication of the practice. What is Mr. Murphy obliged to say at the end of the case? He said like a man yesterday "I give it up, it is explained, I say no more about it, I withdraw that about the sheikh's tomb." It is all very well to say he withdraws that about the sheikh's tomb, but he does not express any regret for it. The only case in which he condescended and endeavoured to make out a case in point of the same sort of misconduct which he imputes in the matter now before us he admits he has been answered about, and as I say like a man he withdraws it, and he withdraws it only when he is answered, and it is only because having men of intelligence to address that he knows he cannot go on with it. The point was gone, there was an end of that charge, and therefore really and truly it comes to this—at least as it seems to me, it is a matter for you of course—if you can put faith in mere denunciation, without a fragment of proof of these charges, if you can think they are made out by mere denunciation, well and good; but if they are not, then really it does come to the one matter in hand, which is very well worth entering into, and which I propose to discuss quietly and shortly with you.

Now, what is it after all that has been done? I cannot help saying that it seems to me evident that in the same way there has been a good deal of exaggeration of the extent that this misconduct—that is, what I will assume for a moment to be misconduct—has injuredthe Central News, or ought to be considered by any fair person. A very gallant fellow does a gallant act, and he, at the hazard of his life if you please, and I dare say it was, got into the works at Tel-el-Kebir and telegraphed home a brilliant account of the transaction. That is forestalled, and the substance of it—not the whole of it by any means, but the substance of it—the number of prisoners, the number of wounded, and the number of guns, which is the important thing. The capture is now given up, I think, or I will not say given up, but at any rate it was disproved, for contemporaneously the fact of the capture was known; but certainly the 40 guns and the 2,000 slain and 2,000 prisoners—whether it was a good or bad estimate I do not know, nor is it material—were not disclosed in any of the contemporaneous, or almost contemporaneous, telegrams. Well, he has done that which many a newspaper correspondent has done before, and which many a newspaper correspondent will do again. It was a very brilliant, energetic thing to do, and he has been forestalled, a thing that has happened to many a newspaper correspondent before and will happen to many a newspaper correspondent again; and that the frightful damage that has been suggested, though it is rather difficult to know exactly to what extent it went—it is said to be at the rate of £1,500 a year that these people were damaged—that that frightful damage is really the result is for you to say by and by. I should have thought that was an extravagant exaggeration; but, however, there it is. I should consider myself that it did not justify the very strong epithets and the very cogent language in which this thing has been put to you, even at the very worst. But only just consider the mode in which this has been launched against these Defendants in this particular case. I have pointed out to you that, prior to this particular case, the only instance that Mr. Murphy or his client have put forward is the case of the sheikh's tomb. In this particular case, unless there was something to show that it was part of a system, Sir James Anderson was as blameless as any one of you. If this was part of a system, then I agree with you that the fact of his absence in Scotland is perfectly immaterial. When I say I agree with you, gentlemen, I mean I agree it would be quite immaterial. But if this is an isolated transaction, and for all that appears in the case it is an isolated transaction, then Sir James Anderson, being away in Scotland, had no more to do with the telegram being sent to him, or with what was done with the telegram when it did come addressed to him, than any one of you gentlemen. Mr. Smith, under circumstances to be discussed presently, does the thing which, for the present purpose, we will call a wrong—he does a wrong thing in Egypt. Mr. Smith is the real sinner, if anybody is. Mr. Smith telegraphs from Alexandria; Sir James Anderson is in Scotland, and this telegram comes to the Defendant Company in London, and the person in charge at the Defendant Company in London, whoever he may be, sends it over to the Exchange Company. So far as Sir James Anderson is concerned in this particular matter he had no more to do with it than you or I. Mr. Smith may have done a wrong thing, but where is the proof (unless there be, what I cannot see, any proof that there was a system of this kind going on), that it was done by conspiracy, or unfair or unlawful means, by Sir James Anderson, or that Sir James Anderson had anything to do with it any more, as I said just now, than any one of us. There is nothing. Surely the sort of language that has been used about him is not justified. You will see, I hope, presently that I do not forget there is another side to the case; but it is disagreeable to me, because, being the judge and trying to hold things equally, I seem to be saying all kinds of things in defence of the Defendants. That is only because my sense of justice—I may be wrong altogether of course—has been offended very much by the sort of unmeasured language in which persons, who up to this time are honourable people (and the facts apparently to my mind give a very different and very honest kind of solution), have been dealt with. I forget what Shakespeare says exactly, but I think it is "Trifles light as air are to the jealous confirmation strong as proof of Holy Writ." I cannot help thinking that trifles light as air have been blown up into proofs of Holy Writ in this case, and that the sort of attack has been made on these people which is not really justified. However, that has been done, and then Mr. Murphy makes a very savage attack—I do not mean to say an attack not within the limits of his duty, or within his breeding as a gentleman, but a very hard and strong attack upon the Defendants for the way in which they have conducted their case, and he says: "You are to draw every sort of abominable conclusion against them because they have answered their interrogatories in a shabby way, and because they have not shown this and that document, and because they have fought *à outrance*, and have not met us in a manly way and disclosed things to us." Gentlemen, the fact is, if you had been in Courts of Justice as long as I have been you would know that in a general way—in a general way I say—if you have got a good case the amount of confidence you can show in it is measured by the amount of light and publicity you let in upon it. There is no doubt (I have not tried both Bars) as is said by a Scotchman, that anybody who has been much at the Bar would know that when he had got a good case honesty is certainly the best policy, and that to show everything and keep back nothing, however unfair and however harsh and hostile may be your opponent, if you have got a good case let him know everything you have got and it will be better for you in the end. No doubt that is so, but then you know everybody is not so wise as we can be who are not engaged in the conflict. It is no use for you or I to look at the matter from our serene heights and say "Oh, if I had been there I should have advised the production of everything." One does not know that one would if one had been there. I think we should, but it is by no means certain that we should have done anything of the kind, and this is to be observed, that when very grave attacks are made upon the character of individuals, as they are here, a man may say "Very well, you choose to impute dishonour and dishonesty to me, prove it. I am not going to help you." It is not wise, perhaps, but that is what nine men out of ten do, and if persons make these attacks, and make these attacks unscrupulously, they must not complain that they are met in the same spirit in which they make the attacks by the Defendants in the case. They must not complain that the Defendants say "Very well, you charge me with dishonesty, you say I did this and that and the other, and that I have been robbing you and stealing this from you—now you prove your case. Whatever advantages the law gives you I shall submit to of course, but not one inch further will I go; you attack me and I do not choose to help you." That really is to my mind the solution—it may not be a very wise solution—of a great deal of the way in which this case has been fought on the part of the Defendants.

Now, certainly I cannot disguise from myself for a moment, and no doubt you have not disguised from yourselves, that some of these interrogatories were most unfortunately answered. At the time when these interrogatories were answered it was perfectly well known that the true source of the information was the Wilson-Malet message, and the identical expressions in it to the message sent must have been known to Mr. Smith, must have been known one cannot help thinking to Sir James Anderson, and probably were very well known to some of the learned counsel who conducted this defence, and no doubt framed some of these interrogatories, or at any rate one of them who framed them. I am not going to scan it with you word by word, because it would be a useless waste of time, I think; but if you scan it word by word and letter by letter it may be literally true by the card, but was certainly so framed as entirely to mislead the Plaintiffs. There cannot be a doubt about it, and it did mislead him, I dare say. Well, that is a great pity; but all that the legal adviser who drew this answer intended was to say as little as ever he could, and to sail as near the wind as he could—not to make him say anything which was absolutely untrue, but if he could say that which was literally and by the card true, and yet would give the opponents no information, so much the better he thought. As I say I do not think that was really wise, but that does not justify, in my opinion, the very strong expressions that have been used. Remember that at the very worst all that has happened is this, that there has been in one case certainly—perhaps in more—an answer misleading; but in other cases there were sources of information. for instance, in the answer I thought it right you should hear yesterday, the existence of their sources of information is pointed out, but they say, "We are not going to tell you; we do not deny we have sources of information, but we are not going to tell you; we claim our privilege

Digitized by Google

not to tell you this," therefore not only implying, but saying there was something to tell, and saying, for reasons good or bad, it is privileged. I do not want to say too much about this, because it makes one sick very often to hear the quantity of fighting over interrogatories which goes on; but still, if we are to talk about the strict law of the case, the Court was to be the judge whether that was or not a satisfactory answer, and whether they were to be protected by privilege from making a better answer. The persons who were dissatisfied with that answer might have come to this Court and said the interrogatory should be better answered, because the privilege insisted on did not exist in point of law. They may have chosen the least of two evils; I do not know but that they acquiesced in the insufficiency of the answer they now complain about, and at least it was fighting with legal weapons in a way which might perhaps have led to a waste of time, but of which they had the legal right to avail themselves. I do not want to use strong language, or to say the English language does not admit of language sufficiently strong to characterise it; but how does it compare with the Plaintiffs, who paid £10 to a clerk to steal a document from the Defendants? I say the Plaintiffs deliberately, because Mr. Burleigh said he had paid the £10, and that has been allowed in account. Therefore, it is not the payment of Mr. Burleigh, but a payment by the Plaintiffs themselves of £10 out of their money, to steal a document from the Defendants, on the ground they say that some wrong had been done to them. Suppose it had. Who can wonder that after that had been done, and after the Defendants knew it had been done, the Defendants held them at arm's length? Does it lie in the Plaintiffs' mouth to say that kind of thing, and to make the sort of speech heard this morning? But things were kept back, say they. Kept back! "Of course," say the Defendants, "when we find you are stealing our documents and paying our servant for stealing them, do you suppose that we are going to trust you." I do not say that even there a very wise and cool headed man would not have said, "They have done a very dirty thing, but that will not prevent me showing them everything." But you cannot very much wonder that the Defendants' backs were put up by that. Do for one moment, as men of sense and experience of the world, put yourselves in the position of the Defendants. Just imagine that a rival of yours, a man in a hostile position to you, had actually gone behind your back and bribed your servant to steal a document of yours that he was going to use against you. What would you say or what would you think if you heard the advocate of that man get up and say, "I do not think so much about the stealing, that is wicked enough, but still, when we have wanted them they have not shown us this, that, and the other?" It is for you, gentlemen. I hope I have not said too much in the course of the case, but I must own my sense of justice has been offended by the way in which prejudice has been rudely and roughly appealed to on one side; and it seems to me the attempt to meet it on the other has been met with a sort of "Oh, yes; it is bad. No doubt we should not have done it; but just look what you are." What is right on one side is right, and what is wrong on one side is wrong, and the same on the other. There cannot be one view applied to one party more than the other. Now I think all this ought to be borne in mind. The fact is that this important document was undoubtedly stolen, was stolen at the instigation of Burleigh, was paid for by the Plaintiffs; and when Mr. Murphy says that Mr. Burleigh was not asked about whether the other documents were stolen, I confess I do not see very much in that, because, as Mr. Burleigh admitted, he paid £10 for this document, and this document, as is not denied, was part of a bundle which has disappeared. I confess I think that it lay rather upon those who called Mr. Burleigh, after Mr. Burleigh had admitted that he paid £10 for one paper on a file, to show that he had not got the rest of that file, because unquestionably and beyond all doubt or dispute that file of papers has disappeared. Although in a criminal case it would not be right to say so, yet I cannot help thinking that this is a fair opportunity for the application of that famous saying, "If Burleigh has not got it, who has?" because the thing has gone. The document was on the file and that file is lost, and we have it that that document has been paid for.

Gentlemen: I dare say there is a great deal more of general observation that might be made upon the case, but really I shrink from making it, because, as I say, my sense of justice has been offended by the manner in which this case has been treated. If I pointed out other things, I might perhaps point out things not so strong, and I might seem to be replying on the summing up of Mr. Murphy, which certainly is not my desire at any time, and certainly is not now.

Gentlemen: Now having made those observations, the question comes as to the two forms in which this case is presented before you. As to the conspiracy, I have already explained to you what conspiracy is, and what the law in respect of it is. The only possible parties, as far as I see, to this alleged conspiracy are Mr. Smith and Sir James Anderson. It is, no doubt, quite possible, if there was evidence of it, that this was merely one of a series of transactions in which Mr. Smith was making use of the news telegraphed by the Plaintiffs, and making use of it really for the benefit of the Defendants, through Sir James Anderson, and that he and Sir James Anderson joined together to do a dishonest and dishonourable thing. I have pointed out to you already that now, with every opportunity of showing that there was a practice, no practice has been attempted. to be shown except in the case of the sheik's tomb, which is given up. Therefore that case stands as an isolated case. If the case stands as an isolated case, unless you think the whole story of Mr. Smith (which is really not now substantially disputed) is untrue, and which I think you will see that the very words of the message itself show in most respects to be unquestionably true—unless that is all moonshine Mr. Smith was no party to any unlawful thing. He may have done an illegal thing, that is for consideration by and by, but that he has done anything morally wrong, or in a moral sense improper, certainly does not seem to be capable of being maintained. If Mr. Smith did not, certainly neither did Sir James Anderson, because it is not suggested that there was any correspondence between them as to this matter beforehand. There certainly was not at the time, because Sir James Anderson was in Scotland, and did not get the telegram. There could not very well have been before, because military operations are proverbially uncertain. Whether the battle of Tel-el-Kebir would be fought, what would be the result of it, and what would be its importance—all those things, like many things, lie in the breast of Providence before they take place, and of course could not possibly be known either to Sir James Anderson, or Mr. Smith, or anybody else; and therefore the notion that there was a conspiracy beforehand between these persons to do this act, which is the only act proved in the case, seems to me, I own, totally without adequate foundation. However, there has been so much said, and so much has been put to you about it, that I certainly shall not withdraw the question of conspiracy from before you. There must be two minds you know to make a conspiracy. One man doing a wrong thing may make himself liable to an action of another sort, but there must be two minds conspiring and agreeing to do a wrong thing before either of them can be guilty of conspiracy; because, as I have explained, the offence of conspiring consists in the unlawful agreement of two minds. One man cannot conspire, that is what it comes to. Therefore, if one man does a wrong thing, though that man may have an action of another sort brought against him, still he cannot have an action in the nature of a conspiracy brought against him.

Then comes the great question which has been chiefly fought in this case, Did the Defendants interfere with any right of property which the Plaintiffs have? Now that is a question of considerable importance, and one not altogether in my judgment free from difficulty. As far as I know with regard to this question of telegraphs, from my impression this is the first case in which the matter has had to be tried, and from the very nature of the case, the recency of the discovery of these things, and still more the recency of the importance of them, and the immense industry that has grown up in relation to them, it is in the nature of the case one of which very little can be known, and it must be decided on principles of common law. Now, it appears to me that there are very considerable difficulties in the way in which the Plaintiffs regard their case, and in the way in which Mr. Murphy has chiefly regarded it. There is a way, and I will tell you what that is in a moment, in which, assuming the facts to be as he assumes them, an action might be capable of being sustained; but I think he has hardly considered the great difficulties that lie in the way of considering this message in the light of a property. He says it is still a property, and that the Defendants in doing what they did interfered with the right of property, which the owners of it can defend, and that if you can suppose such a thing the Courts of Chancery in old days would have interfered by injunction. He likens it to the cases of letters of lectures, and of pictures, and of other things the interference with the right of property in which has been restrained by law in the Courts of Chancery in the former days, and has been made the subject of actions for damages in our Courts of Common Law also in former days. I cannot help observing that there is very considerable difficulty as it appears to me, unless I am mistaken, in his way. I have looked at the parties to this action, and I do not see that Mr. Burleigh is a party to this action, and, unless I have entirely misunderstood the law, the recipient of a letter has no ground of action and no ground of injunction against a person who, between the time when the letter is sent to the recipient and the time he receives it, tampers with that letter. Do I make myself intelligible?

The FOREMAN of the JURY: Quite so, my lord.

The LORD CHIEF JUSTICE: In the time of Lord Coke or Lord Talbot, I forget which, one of the Lord Chancellors in the time of Coke, when Coke went into Chancery to restrain the publication of certain letters, a great judgment was delivered which has settled the law from that time to the present, and I understand the law to be this: If I write you a letter, supposing there to be any literary value in it, mine is the literary property, yours is the paper, and so completely distinct is the property in the paper from the property in the literary composition that you cannot publish my letter without my leave. Although I have sent you a letter by post, and it is your letter as far as the paper is concerned, the contents of it are mine, and I could prevent you by law from publishing my letter if I thought it worth while. Now, that seems to show that the recipient of a letter, and the recipient of a message, has no property in what he so receives. So it strikes me. The sender may have, but the sender is not the plaintiff here. The person who receives the document is the plaintiff, not the person who sends it, and if Mr. Burleigh had a literary property—as it is put upon the footing of Mr. Abernethy's lectures and a variety of other things—in his word picture, Mr. Burleigh is not a plaintiff; and what has been done, even if it has been done wrongly, is as if somebody, between my sending my letter to you and your receiving it, had got hold of it, and thought, either from something in my antecedents or something in the letter itself, it was worth publishing, and before it had got to you had got hold of it in transit and published it. You would not have a right to restrain him by injunction, though I should have a right to restrain him. Therefore, it seems to me—I may be wrong—that there are very considerable legal difficulties in the way in which Mr. Murphy has put this matter as a right of property in the Plaintiffs. The Plaintiffs, as far as I see, in the sense of property have none whatever. There is a ground on which it may be put (I am coming to that directly) that the Plaintiffs' rights of another sort have been interfered with, and in which damage has been done to the Plaintiffs. Mr. Murphy said over and over again, "Mr. Burleigh has as much right in his word picture as Sir Frederick Leighton has in his pictures." I will not say how that may be. All I can say is Mr. Burleigh is not a plaintiff here; he is not bringing the action.

Mr. DICKENS: Will your lordship allow me to say this, in justice to my friend, Mr. Murphy. Mr. Burleigh is one of the directors of the Central News, and, therefore, he would have the property in him as director as well as in his personal capacity.

Digitized by Google

The LORD CHIEF JUSTICE: That is not proved.

Mr. DICKINS: Yes, my lord; Mr. Burleigh was asked the question, and he said he was one of the directors of the Central News.

The ATTORNEY-GENERAL: I do not wish to argue it, but if he is a portion of the entity here, he does not exist on the record in his personal capacity. My learned friend may assume it is proved he is a director; probably that may be accurate.

Mr. DICKENS: We had this point in our minds, and had the point been taken by my learned friend, the Attorney-General, during the time, we should have asked your lordship as matter of form to have added Mr. Burleigh as a party to the record, because it is a mere question of form.

The LORD CHIEF JUSTICE: I do not know that at all. I do not see how Mr. Burleigh could maintain the action on the ground of damages. What damage has it done him?

Mr. DICKENS: Well, my lord, I do not want to argue it now.

The LORD CHIEF JUSTICE: No. I was going over the thing in my own mind, and it appeared to me as far as there was any analogy to the copyright of pictures and the copywright of literary works it fails. That is all I say.

Mr. DICKENS: We had it in our minds, and we thought, rightly or wrongly, the Plaintiffs had a perfect right on that ground. That is a matter for subsequent argument. Will your lordship allow me to reserve any application, if it is necessary to be made, for joining Mr. Burleigh?

The LORD CHIEF JUSTICE: I do not think it would make the least difference in my view. He is not a person on the record. The whole thing then would assume a different aspect perhaps.

Mr. DICKENS: I only ask to reserve it.

The LORD CHIEF JUSTICE: It is a pity it was not taken if you foresaw it. However, I will not argue with you now. I do not understand that either of the learned counsel differs from the principles of law I am laying down to you, gentlemen, and if I am right in the principles of law I am laying down to you—they are quite elementary—the consequences appear to follow. The question of whether a man has a literary property in a message he transmits along an electric cable is, as far as I know, quite new. As far as I am aware literary property, copyright, depends almost entirely—I do not say quite entirely, but almost entirely—upon Acts of Parliament. Certainly as far as I know—I may be wrong—property in lectures depends entirely on an Act of Parliament of comparatively recent time, viz., the 5th and 6th William IV., and only in a very limited way, and with certain incidents which it is not suggested have occurred here. I do not know that it would apply to a case of this kind, but the analogy of that Act altogether fails, because the property given by that Act is of a very limited kind, given under particular circumstances, and given only with certain conditions precedent, which it is not suggested have been or could be followed here. If it was necessary to decide the case upon this simple point—if it was a question of copyright and of literary property in the message—I confess, as at present advised, I should nonsuit the Plaintiffs; I should say there was no ground of action. I do not think it necessary to do that because it appears to me that there is another ground upon which, if the facts warrant it, this action may be sustained, and it is this:—The Defendants are persons who have the control of an electric wire, and the public, and among them the Plaintiffs, deal with them in respect of that electric wire. It must be taken I think (and if it were necessary to find the fact, I have no doubt you would, every one of you, find it in a moment) that persons who deal with the Defendants in messages going along their wire deal upon the understanding, and therefore there is an implied contract between them, that the matter they send shall not be divulged. If you send a message to an intimate friend about a very intimate matter you say nothing about it, but you deal upon the footing that the Government now, and formerly it was the electric telegraph companies in this country, will not tell anybody what you are saying. It must be considered I think to be an implied term of the contract between the sender of the message and the person who sends it, that is in this case between the Plaintiffs and the Defendants, that the message, quite apart from the question of literary property, should not be divulged. That being so I should certainly direct you that if you were of opinion the Defendants had divulged this message sent along their cable by the Plaintiffs to the damage of the Plaintiffs that this action can be sustained. That is my present impression, and according to that present impression I must direct you. It has never yet, as far as I know, been a matter of judicial decision, but that seems to me to be the obvious sense of the thing, and I cannot help believing that what is the sense of the thing is the law of the thing also. Therefore, if you think that there is evidence from which you can make out that the Defendants have divulged the message of the Plaintiffs for which they were paid, and divulged it to the damage of the Plaintiffs, then such damage as you may think has resulted from that divulging they are entitled to recover in this action.

Now, how stands the fact? You must recollect (and I am sorry to be obliged to refer to it so often) how this case was opened. It was opened as a case in which Mr. Smith, in the most fraudulent manner—well, I will say the most unfair manner, for fraudulent I do not like to say, but in the most unfair, and I do not hesitate to say dishonourable manner—had stopped the message of a customer, had extracted the pith of that message for himself, and had sent the pith of it ahead of the customer's message, which was stopped the while in order that it might be forestalled, and that when the customer's message was sent along the line it ceased to be of any value because it had been tapped, and all that was valuable in it had been sent before, and all the labour and trouble and expense had been thrown away. I do not know now very much about trout and worms and so on, but there was a good deal said then about the trout being there waiting for the worm. There was a very picturesque account given of Mr. Smith waiting, and the moment he got hold of this message copying it, and so on. You remember it, no doubt, gentlemen. It was very effective and very amusing, and all this happened, you will not forget, on board the "Chiltern" it was said, and Biancardi has vouched for all this and for the delay of the message. Nothing, in short, could be blacker. It did look black. I must say I believed it all, of course as a man of my age believes everything he hears, especially from the mouth of counsel, and it seemed to demand at any rate some answer. The case went on, and then what turned out at last? Why, what turned out at last was this, that right or wrong (and that we will discuss in a moment), the message that was sent on to London was a message in the very words in which a colonel of the Engineers had telegraphed to the English Minister that that had been got at by the manager of the Defendant Company in transit. I will discuss the minutes presently, but I will assume against the Defendants. I am only assuming it, but I say I will assume it for this purpose, that before it got to Sir Edward Malet the message was sent to London. That is what turns out to be the case now. That, I say, turns out to be the case now, and I am not overstating it I think when I say that you may take it for granted, and I think you will agree with me that that is not fairly in dispute. The Attorney-General said fairly enough, and Mr. Murphy in a manly way admitted, that it was in the very identical words with the exception of the "20 minutes" put in and then struck out a message of some twenty-five or thirty words in the identical words of the Wilson message sent by Mr. Smith to Sir James Anderson. It was a message identically in the words—used in the message from Wilson to Malet, which conclusively proves that one was taken from the other. It was beyond the doctrine of chances that the very same number of words and the very same collocation of words should have occurred to two different minds, and Mr. Murphy did not contest it. What now turns out to be the case was that what was sent on to Alexandria was not any portion—directly at any rate, I will consider the question of indirectly in a moment—of the Plaintiffs' message, but was an independent message, sent from one independent sender to another independent receiver, and, I will assume for the purpose of this part of my summing up, stopped in transit, so to say, and sent on to the man in London. I could not help saying when that was brought to my mind by the evidence of Sir Charles Wilson, and the production of his telegram, and I did say that the great question I should put to you was whether you believed Sir Charles Wilson, because it seemed to me that if you believed Sir Charles Wilson certain consequences would follow, which I will explain presently. It seemed to me that was the cardinal point of the case. Do you believe Sir Charles Wilson's story as to how he telegraphed these words? You will not forget this, that though Mr. Murphy told you he was always anxious to get rid of Biancardi's story the result is this, that after the demonstration that Biancardi's story as to nine-tenths of it was a trumped up fabrication from beginning to end, though there might have been some substance in it, or he might have thought so—you will not forget that Mr. Murphy said, in answer to my appeal to him, because I wanted to shorten the case if I could, "I shall ask the jury to rely on the substantial accuracy of Biancardi's testimony." You will not forget that. So that after Mr. Russell's destruction of Biancardi, as I may call it, and after the evidence of Sir Charles Wilson was given, Mr. Murphy still said he should rely on the substantial accuracy of Biancardi. Now he says he was only anxious to get rid of him. I must say he used language to conceal his thoughts very successfully if he did want to get rid of him, because he said he should rely on the substantial accuracy of what he said in the state of the case to which I have adverted. Not only, you know, is it now admitted that Biancardi's story was untrue, but really nine-tenths of the prejudice of the case has gone. He may have done a right or wrong thing in doing what he did, but recollect how it was opened; recollect the way in which it was put, that this valuable message was retarded and was kept back, and it was suggested even that the Egyptian Government had been got hold of and that this message had been dealt with entirely for the purpose of benefiting the Defendants in the action by Mr. Smith, or Sir James Anderson and Mr. Smith between them, Mr. Smith being in Egypt and Sir James Anderson in London. Now we have got the documents which have been for many days before the very able gentleman representing the Plaintiffs, and what did Mr. Murphy tell us this morning or last night, I forget which? "I cannot deny," says he, "that substantially it is shown that the message was sent in due course." Then what becomes of all this furious attack on Mr. Smith? He may have done a wrong thing in what he admits he did. That may give a ground of action. I do not say at present whether it does or does not; that depends on whether certain facts are found, but the stress of the case is at an end, and I am not wrong in saying that, because Mr. Murphy says it is at an end. He says, "I can no longer rely on nine-tenths of my opening; upon all the prejudice parts of my opening I cannot rely; I cannot rely on its being made out that this man, so abominably as it would be, kept back a message, and took advantage of being there to lock the wire against me, while in the meanwhile he was sending forward something to benefit my rival in trade." That is all gone. You have got the messages, and you have got the messages traced up to Malta, and it is admitted that every single message from 6 o'clock in the morning until 11 o'clock, covering the important time at all events, that went along that system of telegraph wires, beginning at Kassassin and ending at Malta, went in due course. Every single message has been before you, and it is demonstrated that there was no delay. What is the use of these strong and furious attacks upon this gentleman in the opening? What becomes of them? I should have thought it would have been fair to say in reply, "I was misled. That is your fault; you kept back all this from me, and now I see it I give it up, and give up with it a great deal of my personal attack" (I think that would have been only fair to say) "I still say I have got a legal ground against you, I still say that you have done what you had no business to do, and I still maintain my action." That would be perfectly right and proper for him to do. When all or almost all of the personal

Digitized by Google

attacks on which he grounded his opening were not only disproved, but are admitted by him to be disproved, I must say I think it was a little strong to go on with the strong prejudice which he did to the very end of his speech. However that is entirely for him, and not for me.

Now it being proved or admitted—really it is admitted—that there was no dishonesty in the transaction of the message, the case assumes a totally different aspect, and it assumes an aspect which it is very important indeed for you to consider. I do not say that there is nothing at all for you to consider. There is a great deal, but it is a case quite of a different sort to that presented to you at the beginning, and really persevered in to the end. First of all it is said Sir Charles Wilson had no right to read this Burleigh message, and secondly it is said that even if Sir Charles Wilson had a right to read the Burleigh message he had no right to send the substance of it on to Sir Edward Malet, and if he had no right, Mr. Smith had no right to read Sir Charles Wilson's message, and that if Mr. Smith had no right to send the message which he did, so Mr. Smith had no right to send the message which he did, which was a mere copy of Sir Charles Wilson's message. Now with regard to the right of Sir Charles Wilson. I propose to read you, and that is the only part of the evidence I do propose to read to you, what Colonel Webber said, and what Sir Charles Wilson said, because they are both men of character, and men entitled no doubt to the greatest respect at your hands, and then I am going to point out to you what I think must be the sense of the thing according to which you would wish me to direct you. Now this is what Colonel Webber said:—"I am Colonel of Royal Engineers. I was in Egypt in the war. I was on the staff at head-quarters. I was acting as Director of Telegraphs. Up to four o'clock I was in Kassassin, or three o'clock, I am not sure which; after that I rode to the battle. I reached Kassassin on my way back about twelve o'clock. I immediately took charge of the traffic. I arranged the telegrams in the order in which they had been received. They were collected when the station was closed. On the 22nd September I had the telegrams sent to me in a parcel to Cairo, and those at Ismailia were also collected and handed to me." Then he gave the statement about the British military line from Kassassin to Ismailia, and that it ended at Ismailia. From Ismailia to Port Said was the Egyptian line, and at Port Said the line of the Defendants began. Then he says, "I was in charge of the military wire from Kassassin to Port Said. My jurisdiction would cease when the message reached Ismailia. Those who used our wire did not pay for its use. Colonel Methuen was censor. He gave to accredited correspondents blank forms signed by him on which the clerk would send the message, unless there seemed to him to be something glaringly improper. From Ismailia to Port Said it was under the Egyptian Government entirely, and was entirely distinct from our line and from the line of the Eastern Telegraph Company. There was a physical break between the Egyptian line and the Eastern Telegraph Company's line. I do not know that all the messages passed into the hands of Sir Charles Wilson at Ismailia, but it may have been so. Who was in command on that day I do not know. The line had been restored when we arrived at Ismailia, before that time it had broken down. No one, at least in a military position, was instructed to peruse these messages by the English Government at Ismailia before they were sent on. Sir Owen Lanyon very likely saw this message. It would be quite proper that he should. I believe Sir Charles Wilson was living in the same house as Sir Owen Lanyon. He might very likely see it in the same way. They are both well known men, and of high character and position. I can find no record of Sir Charles Wilson's message at Ismailia. Whether it was considered as a Government message, and therefore no record was kept, I do not know."

Mr. MOULTON: He corrects himself, my lord.

The LORD CHIEF JUSTICE: Yes, you are right; I have found it. Then I took a note of what it was. "It was sent from our office in order that it might be franked. The Egyptian Government agreed it seemed that if anything came from one Government to another it should go over the Egyptian line for nothing, and although written at Ismailia, and really it did not come from Kassassin, still it was sent across to the Egyptian station as if it came from the English Government." Then, "There is no time on it," that is not material. Then, "The sending on might have been delayed by censorship. I do not say it was. We have no record of what happened in the Egyptian office. That is lost. I have an entry here of the Wilson-Malet message. Very probably a second copy would not be kept by us when the message went over to the Egyptian line direct." That is when they sent it on, and that explains their having no second copy of it. Then he says, "I had a question put to me and I sent an answer." The rest is not material now, because it is admitted. The question of delay has now been given up. Then in re-examination he says, "Neither Sir Owen Lanyon nor Sir Charles Wilson had any duty that I know of to read a private telegram. I have no official or private document which shows that the news of the victory arrived at Ismailia before this one of Mr. Burleigh. I should say that it did not go through in forty minutes, so it must have been put on after the copy was taken." That is not now material. So much says Colonel Webber. Then later in the case, in consequence of something that I said, for I wished really to know how the matter was, and whether Sir Charles Wilson could tell us what the fact was—in consequence of something I said Sir Charles Wilson appeared here, and properly enough in point of principle said he objected to give evidence as to the source of his information. I do not think he was in the least wrong on general principles, but I do not think that applied to the matter in hand; and so I told him that I thought he should give his evidence. He did so, I think you will say, with perfect propriety. He is a gentleman who did not know or hear of this case, as he said, till a short time before, and has no share in either Company. He is now in this country, in the War Office, and has no interest in the matter except to speak the truth. He says this: "I am a lieutenant-colonel in the Royal Engineers. I was at Ismailia on the 13th September, 1882. I was there on a confidential service for the English Government. It was part of my duty to communicate to Sir Edward Malet all the information I could collect which I thought was of importance for the Government to know. There was a military line between Kassassin and Ismailia, and also a line from Ismailia to Port Said, in the hands of the Egyptian Government. I sent that message to Sir Edward Malet. To the best of my belief this is what I said to Sir Edward Malet." This message has been put in, and you have seen it and heard it read, and I need not trouble you with it again. With the exception of the words "in twenty minutes" every one is identical with Mr. Smith's message. Then "The first information I received"—this is after I overruled his objection to telling us—"of the victory was from a half-breed native named Anololia, who had been my servant for many years. I heard the same account from many of the persons thereabouts. It was general news. I then composed my message, and went over to the tent and sent it. It was not in cipher, as I did not consider the message confidential. I did not authorise any one to use that message before it reached Sir Edward Malet. Then he says, "I knew when I sent my telegram to Sir Edward Malet that the news had been in Ismailia some time, and I sent my telegram on to Sir Edward Malet simply as a matter of duty. I heard it from the members of the staff shortly after. As soon as I was certain that the news was true I went across into the tent. I read some of the messages that were there. I do not remember the long message particularly, but I have no doubt I did read it among others. I had heard of the 40 guns before I went over into the tent. I heard substantially what is in my message before I ever went into the tent. I had probably seen this telegram among others, but I should have sent my telegram as it was without my ever seeing it, and whether I had seen it or no. The military line was open to the officers as well as to Press correspondents. Whether they had received information from the front I am unable to state now. I saw several telegrams. I have no connection whatever with either of the companies. It was information derived from the members of the staff upon which I went into the tent to write my telegram. The telegrams I saw there only confirmed what I had already heard. I had a cipher. I used it at times. I should have used it if I had sent anything secret, or if I thought the matter required to be treated confidentially. I did not use it because this was not a matter I thought required to be secret." I have read you every word of Sir Charles Wilson's evidence, and several observations arise from that. It is a startling proposition, a proposition that I own shocks me a great deal, that in war a military man—a colonel of the Engineers—is not at liberty to read what comes along a military line, a line used by newspaper correspondents, remember, only by favour of the Government, a line laid down without charge except upon the general taxpayer, and used by these newspaper correspondents without paying a halfpenny, and that if there is anything in that message that comes across that military line belonging to the Government that comes to the knowledge of one of Her Majesty's officers he is not to be at liberty to send it on to Her Majesty's ministers. So that if a matter extremely important to be concealed is attempted to be revealed, or a matter that is extremely important to be known is attempted to be sent through without being known, the Government of the country is in such a condition that it cannot look at the telegrams that go along its own Government line, and cannot for Government purposes make use of information it so gets.

Gentlemen, I tell you that is not my understanding of the law. I tell you that in my judgment, unless I am corrected by the House of Lords, I shall continue to think that nonsense. It is perfectly astounding that a newspaper correspondent is to prevent the Government of the country on its own line, which it allows him as a matter of favour to use, from either concealing or revealing information upon parliamentary responsibility alone (because we are all responsible to Parliament) as the Government thinks fit. It seems to me that is quite a monstrous proposition, and when Mr. Murphy said like a man, because he was bound to do it, and he is not a man who shrinks from the consequences, that after Sir Edward Malet had put up that information outside his place at Alexandria, if any man reading it there had sent it to you or me in England he would have been guilty of a breach of the law, I venture to treat that in the same way as I treat the other and call that nonsense, until I am corrected. It is perfectly preposterous, and I cannot imagine its being contended for a moment. It is making the Government exist for the sake of individuals, instead of individuals existing for the sake of the whole country, which is a preposterous idea to my mind, and one that certainly neither here nor in any other position I hold will I permit to pass without strong protest. The interests of the country must be paramount, and persons in the employment of the Government of the country must, subject to parliamentary responsibility, upon their responsibility use the information they have for what they think the public good, and it is idle to my mind to talk about either breach of law or giving a right of action. That is quite preposterous, or it seems to me so at least.

The question now, however, is brought to rather a narrow point. First of all, did Sir Charles Wilson read this message before he sent his telegram? He either did or did not. He says to the best of his belief he did not, and that he should have sent it whether he had seen this or no; that he went to the tent to telegraph what he had already ascertained, and that when he went into the tent he saw a number of messages, and, it may be, this message among them—he will not say he did or did not see it, and very likely he did—but that he did not derive his information from that message, and that he sent his message to Sir Edward Malet as a matter of duty. It seems to me that if he did read it he was clearly within his right in reading it; he had a perfect right to read what had come along the military line. As I said just now, everybody who uses a Government military line in time of war, particularly when it is a matter of favour, and when they are allowed to do it as a matter of grace, must do it with the common sense understanding that the Government have a right to see what they do say.

Digitized by Google

Otherwise the Government line might be made the engine for conspiring treasonably against the Government itself, and there might be all sorts of correspondence sent along the Government lines on the hypothesis that Government had no right to look at, and, if they looked at it, no right to take any advantage of it. That is idle as it seems to me. It seems to me clear Sir Charles Wilson was well within his rights in reading the message, if he did read it. If he did not read it, then he sent on an independent message, and the independent message was sent on by Mr. Smith to London. If he did not read it there is an end of the case as regards Sir Charles Wilson. I mean there is no question that he did anything that anybody could complain of. If he heard a lot of things from his staff, and went and telegraphed to Sir Edward Malet, who is to blame him? He did that which was quite right, and if he had not done it he would not have done what was right. It was his duty to let Sir Edward Malet know as quickly as he could what he knew himself. It seems to me he did quite right in sending on to Sir Edward Malet the information that was in his mind.

Now, it is sent to Alexandria, and at Alexandria it comes on board the "John Pender," and on board the "John Pender" is undoubtedly Mr. Smith, and equally undoubtedly, he being the manager of the line, he saw the message. He does not deny he copied it. The message came, and there was a second line, it is now admitted, as far as Marseilles. I do not know how the matter extends beyond—that was left rather obscure yesterday, but as far as Marseilles there was not the slightest interference with the message of the Plaintiffs. He sent along the second line, Malta No. 1 or Malta No. 2, I forget which, but whichever was the one by which the Plaintiffs' message was sent, the other was the one used to send this message copied from Sir Charles Wilson's message to Sir Edward Malet. Either contemporaneously, that is to say as nearly as possible at the same time or a minute or two later, it was delivered to Sir Edward Malet on shore. Sir Edward Malet's house, it appears, by the time it took to go there as shown by the receipt, must have been very close to the shore office. Sir Edward Malet received it, and Sir Edward Malet immediately did what a Minister does with these things—he immediately published it as far and as wide as he could, and Sir Edward Malet, being perfectly aware of the object of this enquiry, and having heard, as there is no reason to doubt from the date of the letter, for it is December, 1882, that it was put to him for the very purpose of settling if possible a dispute between these rival Companies, Sir Edward Malet got this letter and made this answer:—"Alexandria Station, 18th December, 1882. To Sir Edward B. Malet, K.C.B., H.B.M.'s Agent and Consul-General, Cairo. Sir: The Central News Company, London (Messrs. Burleigh and McDonald, late special correspondents in Egypt), having alleged that news was abstracted from their telegrams which passed through this station, and more particularly from those which contained news of the battle of Tel-el-Kebir, and in consequence threatened me with legal proceedings, I have the honour to request you to have the goodness to inform me if the telegram you received from Sir C. Wilson on the 13th September last, announcing a battle and a victory to the British army at Tel-el-Kebir, was published, or in any way made public by you shortly after its receipt. I have the honour to be, sir, your humble, obedient servant, B. Smith, Acting Manager." Then Sir Edward Malet, in reply, writes this letter, dated 20th December, to Mr. Smith:—"Cairo, December 20, 1882. Sir: I beg to acknowledge the receipt of your two letters, numbered 777 and 779, of the 18th instant, in the first of which you ask me whether I published, or in any way made public the news of the battle of Tel-el-Kebir shortly after the receipt of a telegram from Sir Charles Wilson announcing it. I beg to inform you in reply that I made the news public by all means at my disposal as soon as I received the telegram." So you have Sir Charles Wilson's saying:—"I did not use the cipher, because I did not consider it confidential," and what Sir Edward Malet does is to publish it to the world as soon as he receives it, so that he did not consider it confidential, and when one hears the words used, "a private telegram," and a confidential communication of a great victory of Her Majesty's troops from one officer in Her Majesty's army to an ambassador in Her Majesty's service, one wants to know what is the meaning of language—a secret communication of a great battle from a military officer to an ambassador! Certainly that is irrational. Then he goes on: "In reply to your second letter, asking me how I communicated the news to Sir Evelyn Wood, and enclosing a certified copy of words found written in pencil on the wall of a room in Count Zizinia's house at Ramleh, I beg to state that I sent the message to General Sir E. Wood by telephone immediately after the receipt of the news from Sir Charles Wilson on the morning of the 13th September last. The certificate enclosed in your letter is herewith returned. I am, Sir, your obedient humble servant, E. B. Malet." I think that that latter part is immaterial, and you need not be troubled about it. I do not know what bearing it has on the case; I suppose none. I only read it as it is part of the letter. That is what happened. Now as to Mr. Smith. Mr. Smith certainly did a thing which, as he said himself, at an ordinary time he would not have done. Of course, it is obvious that a message from one high official to another, if you become acquainted with it, even if it is not a secret message, as this certainly was not, even if it is only asking after his health or any perfectly indifferent matter, it is obvious that you would not take it and telegraph it on to London. That is manifest, and it is not a thing that Mr. Smith either would or could do with propriety in a general way. There is no doubt in the world about that, but, as he said, and I think with some sense, the circumstances of the case must be considered. Alexandria—not the city, but the ports—had been bombarded, there had been a massacre, the times were out of joint, there had been a great battle, the troops were advancing on Cairo, and the English public and every Englishman there was intensely interested, no doubt, in the result of that, and in knowing the facts. Mr. Smith, upon the highest authority—Sir Charles Wilson—had got a short, telling, clear telegram, announcing the victory. That came to his hands, it was sent along his line; he was there in his position as manager, and must have read it for the purpose of sending it on. There was no harm in his reading it; that he must do, for he had to send it on from the ship to Sir Edward Malet. Then either before or after—and it seems to me profoundly indifferent whether a minute or two before or after, but either before or after, and certainly without Sir Edward Malet's leave, he sent on the message along another wire to London; it is received in London, and has no doubt the effect of coming before the long message of the Plaintiffs. Who complains? The Plaintiffs complain, and have a right to complain if they are interfered with. But whose right is interfered with? I tell you, gentlemen, that as far as I can see, if you believe Sir Charles Wilson, no right of theirs was interfered with, because Sir Charles Wilson tells you he had a right—that he thought it his duty, and it clearly was his duty—to read the messages that came from Kassassin to Ismalia. He says that whether he had read this message or not he cannot tell, but he certainly did not use it for his telegram, because he knew it all before he went in the tent and saw it; but whether he read it or whether he did not read it—whether he made use of it or did not make use of it—it seems to me that Sir Charles Wilson, in the position in which he was, was perfectly right to telegraph it on to Sir Edward Malet. In the course of transmission to Sir Edward Malet it gets into the hands of Mr. Smith, and Mr. Smith makes a use of it which I will assume, if you please, as against Sir Charles Wilson, would have been a wrong use. That is a use which, if Sir Charles Wilson chooses to complain of it he might—well, I really will not say, we are not trying that action, I do not know how he could frame his case—but he might say, "You have no right to make use of that till it got to the recipient's hands and you got the recipient's leave." That may be, but that is a breach of duty of which Sir Charles Wilson or Sir Edward Malet, one of the two, is the only person that can complain, and certainly not the Plaintiff Company, because Sir Charles Wilson was only doing what he had a right to do; and as Sir Charles Wilson was only doing what he had a right to do, then Mr. Smith, the agent of the Defendants, was doing that which was possibly a thing which, as I say, either Sir Charles Wilson or Sir Edward Malet might have complained of, but which, as it was no wrong to the Plaintiffs, can form no ground of action against the Defendants. Therefore, it comes to this, that it seems to me the point really does come back to the question of whether you believe the evidence of Sir Charles Wilson. In saying that that is the question, of course I do not for a moment suppose that anybody would think that Sir Charles Wilson intended to deceive us, for he has no kind of object in deceiving us. He is a man of high and blameless character; a man in the service of his country, to which he has rendered great service, and may render still more, and a man who comes here, not as the witness of either side, but coerced by the judge, and so made to give his evidence against his own will by the judge on the bench, for as you know he did not wish to say a word about it, and it was only when I told him he ought to tell us that he told us what you have heard, and therefore a witness more free from suspicion, and a witness more absolutely entitled to belief as far as intention goes I cannot imagine. He was a witness not for either side, but his evidence was drawn from him by the Court in the interests as I thought of justice. None of us knew, of course, what he would say when he came here to say what happened.

Now, gentlemen, I had not thought of saying a word about these telegrams and other things that have been mentioned, but as I have got it down on paper, do just see the sort of way in which the case against these Defendants is presented. There is a telegram to Gibbs from Hardman of the 12th of May, 1883. This is suggested to you as a ground why you should think there has been foul play on the part of the Eastern Telegraph Company. This is addressed to Mr. Gibbs by their manager in London as I understand:—"I hope you are right, but the Governments of Europe have the affair now in hand, and it is their business. I must strongly caution you not to take any side, or to become known as any partisan. If the Powers prevail Arabi and his supporters may be great danger to you. Egyptian stock advancing." Mr. Murphy read that to you as if it was a very suspicious thing, but he read it in a very different way. The rest of the sentence is this:—"Egyptian stock advancing strong evidence that the European Powers will interfere." He had said, you know, "Take care, it is an affair of the Powers, and do not make yourself a partisan," and then he goes on, "Keep me advised, your messages will always be sent to head-quarters."

Now, really is that so very suspicious and desperate a message to have been sent to that person in May, 1883? It is sent to Gibbs in Alexandria, telling him, as a reason why the parties in London think the European Powers are going to interfere in a body, that the Stock Exchange shows Egyptian stock is advancing. Is that a suggestion that there was no complication going on in Egyptian stock, or is not the fair interpretation of that this, that this matter is going to be taken up by the European Powers, and as a proof of it Egyptian stock is rising in the market; take care what you are about, and do not be a partisan, because you may get into difficulties. I only happen to have that here because it is one of the last things put in, and you remember how Mr. Murphy used it. I will not trouble more about that.

Gentlemen, this is the case. The prejudice in the case is enormous, but the facts are singularly few. As I say, the question seems to me to be this, and it is the question I shall leave to you. Do you believe that Sir Charles Wilson made use of the Burleigh message in framing his telegram to Sir Edward Malet? Then I shall leave to you, supposing that on the facts of the case a verdict for the Plaintiffs can be sustained (which is a matter I reserve entirely for further argument), for what damages do you find your verdict? That is supposing there should be a verdict capable of being sustained for the Plaintiffs. I should like you to answer my question first, whether Sir Charles Wilson made use of the Burleigh message in framing his telegram to Sir Edward Malet.

The Attorney-General: Late as it is, my lord, would you allow Mr. Burleigh now to hand in the name of the clerk?

Digitized by Google

The LORD CHIEF JUSTICE: Yes. Mr. Burleigh was to do that. I should think it would be enough if he would say whether that is the name mentioned in Biancardi's paper. It is quite sufficient if he says that is the man.

Mr. DICKENS: Mr. Burleigh does not happen to be in court at the present moment.

The LORD CHIEF JUSTICE: You know, I dare say, Mr. Dickens.

Mr. DICKENS: No, I do not, my lord, I never heard it. Mr. Burleigh has been communicated with.

The LORD CHIEF JUSTICE: It will be quite enough if he says that is the man; it is probable he is, but it is much better to have it authenticated by him. I think it right to say that the ground on which I act in desiring the name is not so much to hunt the particulars out, but to relieve all the others from suspicion.

Mr. DICKENS: That is what I understand, my lord.

The LORD CHIEF JUSTICE: Otherwise they would all remain under that suspicion. You would probably like to retire, gentlemen?

The FOREMAN of the JURY: Yes, my lord.

The ATTORNEY-GENERAL: Your lordship expressed an opinion as matter of law that there would be an implied term in the contract not to disclose information that passed through the wire of the Company by which it carried it for its customers.

The LORD CHIEF JUSTICE: I did.

The ATTORNEY-GENERAL: I am not dissenting from that proposition, but I want to point out, lest it be said the point was not mentioned at all, that this contract is an Egyptian contract. There is no contract in this country. It is made at Port Said, and any alleged breach of it took place at Alexandria. If that is so the law of the place of the contract must prevail, and I wish to reserve to myself this, that there is a total absence of any proof of what is the Egyptian law in relation to a contract of this kind, and that it does not of course follow that the Egyptian law, assuming your lordship to be right, which with respect I do, will affect the Egyptian contract.

The LORD CHIEF JUSTICE: Either party shall have every opportunity of arguing anything they like.

The ATTORNEY-GENERAL: I thought my learned friend might say this has not been called attention to, and that we ought to regard it as an English contract.

Mr. DICKENS: I shall submit that it is too late for my learned friend the Attorney-General to take that point when the case is over.

The LORD CHIEF JUSTICE: It is an objection to my ruling, you see.

Mr. DICKENS: Upon that point your lordship said to the jury, I think, in summing up, that if they thought the Defendants had divulged the message to the damage of the Plaintiffs that then the Plaintiffs would be entitled to the verdict.

The LORD CHIEF JUSTICE: Would be entitled to maintain an action I said.

Mr. DICKENS: Your lordship did not put that question to the jury.

The LORD CHIEF JUSTICE: Yes.

Mr. DICKENS: I understood your lordship left only the question whether they believed Sir Charles Wilson.

The LORD CHIEF JUSTICE: I told them that, supposing on the facts of the case—it is included in this, I think—if the verdict for the Plaintiffs can be sustained, what damages do they find; that is to prevent its coming back again.

Mr. DICKENS: With submission I should have thought it would have been safer to put that question to the jury.

The ATTORNEY-GENERAL: It is put, really.

The LORD CHIEF JUSTICE: I thought I really did put it. I said that no man could suggest now that the message came from anything but the Wilson-Malet message. I said I thought the doctrine of chance was so irresistible against two minds having used the same form of words that the inference was irresistible that one was copied from the other.

Mr. DICKENS: I understand my friend Mr. Murphy's point to be this, that Mr. Smith received and read this message and knew perfectly well Sir Charles Wilson's was a summary of our message, and sent it on as a summary of our message, knowing it perfectly well, and so divulged our news.

The LORD CHIEF JUSTICE: That you were taken advantage of. I do not agree to that. He had either the right or not to use Sir Charles Wilson's message. He had not the least right, because it actually represented something else.

Mr. DICKENS: Of course that is a matter for argument. With submission to your lordship, I would submit that the question to be put to the jury, besides the question your lordship has put, is whether or not they did divulge the news to the damage of the Plaintiffs.

The LORD CHIEF JUSTICE: I told them if they did an action could be maintained in my judgment.

Mr. DICKENS: I am afraid the jury in a complicated case like this will hardly follow that. Your lordship finished by asking them only one question—whether they believed Sir Charles Wilson. I should respectfully ask your lordship to put that question I suggest.

The LORD CHIEF JUSTICE: I suppose I had better put it, because if I do not somebody will say I ought to, and then there will be a new trial. I do not think it necessary.

Mr. DICKENS: If your lordship thinks not——

The LORD CHIEF JUSTICE: I do not think it necessary in the least, but somebody else may. What is it you say should be put? I have a difficulty in following you honestly. Is it that if the Burleigh message had not existed he would have had a right to telegraph on the Wilson message, as least as regards the Plaintiffs; but inasmuch as the Wilson message did contain that which the Burleigh message contained, and if Mr. Smith had read the Burleigh message before he read the Wilson message, therefore that is evidence that by sending on Wilson's message he divulged the Plaintiffs'? No, I think not. I do not think that is so.

Mr. DICKENS: I was struck with the way your lordship put it. If you will allow me to say so, your lordship put the question to the jury pointedly, "If you think they divulged the Plaintiffs' message to the damage of the Plaintiffs, that is a cause of action," and it struck me that was a question your lordship would leave to the jury.

The LORD CHIEF JUSTICE: What I was trying to do was this. I did not agree, though I may be wrong, with the way in which Mr. Murphy has put it, but still I thought the action was maintainable in another way supposing the facts warranted it. But then, if they believe Sir Charles Wilson, the facts do not warrant it.

Mr. DICKENS: I do not wish to argue it at the present time.

The LORD CHIEF JUSTICE: But I wish you to, Mr. Dickens.

Mr. DICKENS: If I begin to argue it I am afraid I must argue the whole question of law.

The LORD CHIEF JUSTICE: Say anything you can to persuade me to put that question. At present it strikes me, if they believe Sir Charles Wilson did not make use of the Burleigh message, then I am of opinion the sending of the Sir Charles Wilson message to London was no cause of action on the part of the Plaintiffs. If I am wrong that must be set right, but that is my opinion.

Mr. DICKENS: I will put it in this way. If the jury find Sir Charles Wilson did not see our message at all, or take it from our message, then there might be a question whether there was any cause of action. If he did take it from our message, a very important question would arise whether or not, when Mr. Smith took what he did, he did not actually take our own.

The LORD CHIEF JUSTICE: If there are two independent sources, and a man makes use of one, I cannot see that that matters to the other.

Mr. DICKENS: If Sir Charles Wilson took our property he could not divest us of our right of property; he could only take it for the specific purpose of sending on to Sir Edward Malet; and if Mr. Smith, on the way, and before that message got to Sir Edward Malet at all, took our message, he interfered with our right of property. That is what I should submit, and it is upon the evidence that he did take it before he sent it to Sir Edward Malet at all. I say no more than I have.

The LORD CHIEF JUSTICE: You wish me to ask the jury if they disclosed your message. I must tell them that I think there is no evidence of it.

Mr. DICKENS: I ask your lordship not to do that, for I submit there is.

The LORD CHIEF JUSTICE: I must tell them that.

Mr. DICKENS: If your lordship is going to tell them that, I would rather you did not put the question.

The LORD CHIEF JUSTICE: You are a little impatient, Mr. Dickens. I was going to say I should tell them there is no evidence of it if they think Sir Charles Wilson did not read the Burleigh message.

The ATTORNEY-GENERAL: If Biancardi's statement is untrue, there is no evidence of it at Alexandria.

The LORD CHIEF JUSTICE: No.

Mr. DICKENS: I quite admit, if Sir Charles Wilson did not read our telegram, and never saw it, there might be a different question; but that is one of the questions the jury have to answer.

The LORD CHIEF JUSTICE: That I have left to them.

Mr. DICKENS: Supposing they say Sir Charles Wilson did read our message, is that sufficient for argument afterwards?

The LORD CHIEF JUSTICE: I did not say "read"—I said "make use of."

Mr. DICKENS: Supposing the jury find Sir Charles Wilson as a matter of fact made use of our telegram?

The LORD CHIEF JUSTICE: Then I will leave you to argue it. I do not mean to do anything at present.

Mr. DICKENS: Then, my lord, I should submit the proper question has not been left to the jury. It is left incomplete. I will not take up time about it. I thought it right to call attention to that.

The LORD CHIEF JUSTICE: I must say that upon that I will leave it to the jury, with my comment that there is no evidence of that if they believe Sir Charles Wilson did not make use of the telegram. I will do that with pleasure, and will send for the jury at once.

[The jury having been sent for returned into court.]

The LORD CHIEF JUSTICE: It is very desirable, gentlemen, that there should be no miscarriage. It is suggested I should put another question to you. I do not think it important myself, but it is very much better to to put it in case there is any trouble afterwards. I think it is involved in what I have already left to you, namely:—Do you believe that Sir Charles Wilson made use of the Burleigh message in framing his telegram to Sir Edward Malet. That in my judgment seems to raise the whole point of the case, but it is desirable I should put to you also this: I have already said that if the Defendants divulged the Plaintiffs' message to their damage—it is also said to be very doubtful whether that would give an action under the circumstances, but I tell you for the purposes of today that would give an action. And then they say I had better ask you, did the Defendants divulge the Plaintiffs' message to the damage of the Plaintiffs? I must add, to show that I did not mean to withhold it from you at all, this—I tell you in point of law that if you think Sir Charles Wilson did not make use of the Plaintiffs' message in framing his telegram to Sir Edward Malet there is no evidence of such divulgence. It seems to me to be involved in the other question. If you think Sir Charles Wilson made no use of the Plaintiffs' message in framing his telegram, I think you ought to find on this question as a matter of law that the Defendants did not divulge it. I think it is involved in the question I have put already.

A JUROR: Would your lordship tell us again the second question?

The LORD CHIEF JUSTICE: The question that I am desired to put, and I put it with with some reluctance, merely because somebody else may say I did not do it, is this:—Did the Defendants divulge the Plaintiffs' message to the damage of the Plaintiffs; and I must add to you this direction

Digitized by Google

in point of law, and I have written it down so that there shall be no sort of doubt what I did say. I tell you if you think Sir Charles Wilson did not make use of the Plaintiffs' message in framing his telegram to Sir Edward Malet, that there is no evidence of such divulgence. Therefore, it really and truly is involved in what I have left to you already; it is only to save more trouble I put it now.

The jury then retired.

The ATTORNEY-GENERAL: It will be open of course to the Defendants to contend that there is no evidence to go to the jury in support of the affirmative answer, if it should be given, to the question which your lordship has just left to them.

The LORD CHIEF JUSTICE: Certainly.

The ATTORNEY-GENERAL: That must be taken as a point on the motion for judgment.

The LORD CHIEF JUSTICE: Yes.

The ATTORNEY-GENERAL: I am sorry to refer to this question again, but Mr. Burleigh has been in the neighbourhood of this court, and he should come in and give the information we want.

Mr. DICKENS: Mr. Burleigh has been told that he is wanted. My client has told him that the Attorney-General wants him. As far as we are concerned we can do no more.

The LORD CHIEF JUSTICE: There ought to be no difficulty about it. You will take it from Mr. Murphy or from his clients.

The ATTORNEY-GENERAL: Of course I would take it from my learned friend's client, but that gentleman does not know the name, and does not wish to be under any responsibility. Mr. Burleigh was in court a few minutes ago, I am told, and went out.

The LORD CHIEF JUSTICE: It would be sufficient if any body representing the Plaintiffs would give it, I should think.

Mr. DICKENS: We do not know it—none of us.

The ATTORNEY-GENERAL: I am sorry to have to do so, but really I should ask that the jury should not be discharged until Mr. Burleigh appears. He is within hearing, I believe. He has been in court within the last few minutes.

The LORD CHIEF JUSTICE: Of course. Mr. Burleigh must come. I will have him called outside.

[Mr. Burleigh was called, but did not answer.]

The LORD CHIEF JUSTICE: Mr. Burleigh must be sent for. I do not mean to be trifled with. He must be sent for, and the jury will be kept until he comes.

Mr. DICKENS: I quite understand that, my lord.

[The jury returned into court at four minutes to two.]

The LORD CHIEF JUSTICE: Before you give your verdict, gentlemen, I must ask one question—Is Mr. Burleigh here?

Mr. DICKENS: I am told he is not here, my lord.

Mr. MURPHY: My client does not see him here.

The LORD CHIEF JUSTICE: I am sorry to detain you, gentlemen, but I must not discharge you yet. Mr. Burleigh has not yet appeared to make the statement required of him, and I must not discharge you until he does.

The ATTORNEY-GENERAL: I acted on my client's view at the moment just now that Mr. Burleigh had been in court. My client thinks he may have made a mistake, therefore I wish to withdraw the expression that Mr. Burleigh was in court and left it.

The LORD CHIEF JUSTICE: Very well. Is it not tolerably certain that the name in Biancardi's paper is the one?

Mr. MURPHY: I have not the slightest notion, my lord.

The ATTORNEY-GENERAL: I do not know that your lordship would lose jurisdiction over Mr. Burleigh if you made a request that he should attend before your lordship, even if the jury do give their verdict.

The LORD CHIEF JUSTICE: I do not know; if the jury have given their verdict and are discharged the case is over, and he is like any one of her Majesty's subjects then. At present the case is progressing.

The ATTORNEY-GENERAL: With submission, if you direct a person to attend as a witness and he does not attend your lordship would have jurisdiction over him.

The LORD CHIEF JUSTICE: Mr. Burleigh is not here, Mr. Murphy?

Mr. MURPHY: No, my lord, he was here yesterday afternoon; I think I saw him.

The LORD CHIEF JUSTICE: I dare say it is a mere misapprehension. Would your Company undertake to tell the Defendants the name?

Mr. MURPHY: I must decline to pledge my Company to anything in this matter. I do not know the name, and the solicitor who instructs me does not know the name, and I do not think any body does but Mr. Burleigh.

The LORD CHIEF JUSTICE: I did not mean to ask you personally, but whether there was any reasonable doubt that your Company would undertake to give the name.

Mr. MURPHY: We have no control over Mr. Burleigh; he might or might not carry out any undertaking given on his behalf. This is a matter I must decline to enter into.

The LORD CHIEF JUSTICE: I understand; I do not blame you in the least degree. I was merely asking whether it was not highly probable that the name mentioned by Biancardi was the name?

Mr. MURPHY: That I do not know. I have not asked the question.

The LORD CHIEF JUSTICE: I am very sorry to keep you, gentlemen, but it is important we should have if we can the name of that clerk, not so much for any injury to him, but that all the others may be free from the suspicion which it is but reasonable they should lie under now. I have jurisdiction over Mr. Burleigh until your verdict has been given. Mr. Burleigh is not here now, and it is not certain whether he has been in court this morning; at all events it is doubtful, though he was here yesterday. It may be a mere misapprehension of course. He did say, if I recollect rightly, in the box that if he was pressed he would give it.

Mr. MURPHY: Yes, to your lordship and the jury, I think he said; I am not quite certain of his words.

The ATTORNEY-GENERAL: Yes.

Mr. MURPHY: He gave a reason why it should not be asked for; but I understood him to say if he was ordered to give it he would, not otherwise.

The LORD CHIEF JUSTICE: Yes, it was waived at that time.

The ATTORNEY-GENERAL: If your lordship made an order upon him to give it he would no doubt.

The LORD CHIEF JUSTICE: I do not want to keep the jury. Will this do; suppose I make an order in the hearing of the parties upon Mr. Burleigh to give the name?

The ATTORNEY-GENERAL: I shall be satisfied with that.

Mr. MURPHY: I can see at once I have no means of enforcing it.

The LORD CHIEF JUSTICE: I do not want to embarrass you in any way, Mr. Murphy.

The ATTORNEY-GENERAL: It would be quite satisfactory to me for your lordship merely to direct that in pursuance of his promise he give it, and we will endeavour to obtain it.

The LORD CHIEF JUSTICE: Then I make the order. I order Mr. Burleigh as if he were in the box to communicate the name of the clerk from whom he received that paper. Now I will take your verdict, gentlemen.

The FOREMAN of the JURY: My Lord, we have confined ourselves entirely to answering the two questions put before us. I will read the first question, "Do you believe that Sir Charles Wilson made use of the Burleigh message in framing his telegram?" Our answer is, "We believe that Sir Charles Wilson did make use of the Burleigh message indirectly." The second question we understand to be this, "Did the Defendants divulge the Burleigh message to the damage of the Plaintiffs?" We believe not.

The LORD CHIEF JUSTICE: Then I need ask nothing further.

The ATTORNEY-GENERAL: No, my lord.

The LORD CHIEF JUSTICE: Then I will hear this or further consideration on a future day as to what judgment should be entered.

The ATTORNEY-GENERAL: If your lordship pleases.

Mr. MURPHY: I did not hear the precise question put as to the second point; was it confined to Sir Charles Wilson?

The LORD CHIEF JUSTICE: The foreman read exactly what I put; he wrote it down, I think. Did you take it down, Sir?

The FOREMAN: Yes.

The ATTORNEY-GENERAL: May I ask whether on that second finding there is any doubt or question for argument, and whether the Defendants are not entitled to judgment?

The LORD CHIEF JUSTICE: No, I shall have it argued. I think it better. Upon the two findings, I think it better to have it argued.

Mr. MURPHY: Has your lordship taken the opinion of the jury on the question of damages, in the event of my being entitled to the judgment? I submit that ought to be done.

The LORD CHIEF JUSTICE: I asked them, supposing on the facts of the case a verdict for the Plaintiffs can be sustained, what damages do they find?

Mr. MURPHY: Have they answered that?

The FOREMAN: We did not take that into consideration because we thought every thing was subordinate to the two general questions.

Mr. MURPHY: I submit the damages ought to be assessed contingently, in any event to prevent this case possibly being tried again.

The LORD CHIEF JUSTICE: If you put me to it, I think not. If the jury, without much trouble, can fix it, it might save a difficulty, but I do not want to keep them here all day.

A JUROR: Does not the second question answer it, my lord?

The LORD CHIEF JUSTICE: I should have said so, but now a ten days' trial is only the first act in a prolonged drama. I want to avoid this coming down again, if possible.

A JUROR: What will be the question?

The LORD CHIEF JUSTICE: Supposing on the facts of the case a verdict for the Plaintiffs can be sustained, for what damages do you find?

Mr. MURPHY: May I suggest the question I should like put?

The LORD CHIEF JUSTICE: Yes.

Mr. MURPHY: Assuming the Plaintiffs are entitled, as against the Eastern Telegraph Company and the Exchange, to complain of the publication of that telegram, what damages?

The LORD CHIEF JUSTICE: No; I will not put that.

The ATTORNEY-GENERAL: I have no objection to that. They find he did not, as it seems to me.

The LORD CHIEF JUSTICE: I will not put that. I will put this—Supposing on the facts of the case a verdict for the Plaintiffs can be sustained, what damages?

Mr. MURPHY: I claim, in order that that question may properly be put to the jury, a direction, so that the jury may not be assessing damages with respect to the act of Sir Charles Wilson, as distinguished from the act of the Defendants.

The LORD CHIEF JUSTICE: You must get a shorthand writer's note of my summing up. I have given a very full direction, I think.

A JUROR: Would your lordship kindly repeat the question?

The LORD CHIEF JUSTICE: Supposing on the facts of the case a verdict for the Plaintiffs can be sustained, for what damages do you find?

The ATTORNEY-GENERAL: With great submission I would ask your lordship to direct the jury whether the damages are to be assessed on account of the divulging of Sir Charles Wilson's message, or on account of the divulging of the Plaintiffs', which the jury have found they did not divulge. It makes all the difference in the *quantum* of damages. The *quantum* of damages must be different if it was the divulgence of Sir Charles Wilson's message made up of other things but the Plaintiffs' pure and simple. They have found the Defendants did not divulge the Plaintiffs', and therefore it requires a direction on the *quantum* of damages, I

Digitized by Google

submit, or else the jury may be at large as to what the damages to be assessed are.

The LORD CHIEF JUSTICE: For myself, I think you had better stand upon the finding as it is.

The ATTORNEY-GENERAL: If your lordship pleases.

The LORD CHIEF JUSTICE: Then I will not trouble you about the damages gentlemen, I will consider you have answered the question. I reserve this case for further consideration.

Mr. MOULTON: May I ask your lordship with regard to the costs that they should be on the higher scale, and that the shorthand notes should be allowed as part of the costs. I believe my application must be made actually at the trial.

Mr. MURPHY: I have not heard any judgment given yet. I do not see how the question of costs has arisen yet. I shall still hope to show that your lordship's judgment ought to be entered for the plaintiffs.

The LORD CHIEF JUSTICE: You want a certificate for a special jury, I suppose?

Mr. MOULTON: Yes.

The LORD CHIEF JUSTICE: Is it your special jury, Mr. Murphy?

Mr. MURPHY: I do not know; whichever it is, of course, there should be a certificate for a special jury.

The LORD CHIEF JUSTICE: The words are, "Shall at the trial of the cause, whether the cause or matter shall or shall not be brought to trial, or further consideration order," and so on.

Mr. MURPHY: I should have thought the further consideration was part of the trial, but it is quite immaterial.

The LORD CHIEF JUSTICE: It says it is to be done at the trial whether further consideration or no.

Mr. MURPHY: With reference to the application as to the shorthand notes, I would only remind your lordship of this, that the Court of Appeal has laid down specific rules about this matter. If people want shorthand notes they must take them on their own account.

The LORD CHIEF JUSTICE: Yes.

Mr. MURPHY: There has been no reference made to the shorthand notes.

The LORD CHIEF JUSTICE: I am going to decide in your favour without hearing you, Mr. Murphy, so strong do I think your case.

Mr. MURPHY: Then I had better sit down.

The LORD CHIEF JUSTICE: At present I am with you.

Mr. BOMPAS: Upon the other question of the higher scale, what does your lordship say?

The LORD CHIEF JUSTICE: I think the costs should be on the higher scale, but I cannot allow the shorthand notes. That is a luxury for which you must pay.

## GREAT NORTHERN TELEGRAPH COMPANY OF COPENHAGEN.

Abridged report of the annual general meeting held at Copenhagen on the 26th April, F. Zahle, Esq., presiding.

The Chairman, C. F. Tietgen, Esq., in opening his address to the meeting with regard to the Company's business during the past year, remarked that he saw no occasion to tire those present with a specific list of the different interruptions of the Company's cables, the more so as these interruptions had not interfered either with the Company's capability to transmit the traffic as usual, or with the ordinary receipts accruing from the latter. Notwithstanding these interruptions, of which the greater part occurred in the latter half of the year, the condition of the cables had, on the whole, been satisfactory, and the engineers had, with the help of the Company's ships, effected the repairs very promptly, and also effectually supervised the state of the cables. What had, however, contributed most to the equanimity with which the directors could look upon these interruptions was mainly the progress made in the perfectioning of the Company's system which had taken place last year, partly by the duplication of the Hong Kong-Shanghai cable, which had been undertaken by the Eastern Extension Telegraph Company, partly, and mainly, by the Company's duplication of the cables between Shanghai, Nagasaki, and Wladiwostock. The new Hong Kong-Shanghai cable was already opened for traffic between these two places on the 23rd May, and on the 18th of June it was further carried into Foochow, thus bringing this important commercial place into connection with the Company's cable system. The manufacture of this Company's new Shanghai-Nagasaki-Wladiwostock cables was commenced in January last year by the Telegraph Construction and Maintenance Company, in London, under the supervision of the Company's engineers. The cables were then shipped on board and successfully laid from that Company's cable steamers, the "Scotia" and the "Seine," and all connections were finally completed in September. The Company had further undertaken, for their own account, the establishment of a cable communication between Japan and Corea, a cable which starts from the eastern coast of the Island of Kiusiu, connecting Nagasaki with Fusan on the western coast of Corea and touching at the Islands of Iki and Tsusima. It was owing to a convention between Japan and Corea that the Company had been placed in the position to connect telegraphically these two countries, of which the latter had lately been opened to Europeans. What the financial result of this undertaking would be for the Company depended, of course, upon the future development of Corea. In Europe the Company had also laid a new cable, viz., between Sweden and Russia, thus triplicating the existing connection. This cable, which had been laid in the month of September by the Company's own steamer, the "H. C. Œrsted," will henceforth be the means of greater security on a route which is of great importance to the Company, and where repairs to cables in winter time, while the Gulf of Bothnia is covered with ice, can only be effected with great difficulty. On the whole, it would be seen that the Company had, during the past year, besides giving their full attention to the development of the traffic, also shown great activity in rendering the whole cable system as complete as possible. The number of the Company's cables now amounted to 17, not reckoning intermediate sections, and the total length of the same was 6,162 nautical miles. All the cables in the far East had, as it were, been duplicated, and although the original cables, now 13 years old, had constantly been maintained and renewed as occasion arose, the knowledge of the existence of a duplication by new and strong cables would be very reassuring to the shareholders. The confident expectations as to the future financial results which the Board expressed at the last general meeting had been justified. As the statistics would show, the gross telegraph receipts for the past year had been 6,362,200 francs, about £255,000, or about £13,200 more than in 1882. This satisfactory increase had not only been owing to the effects of the duplication itself, as referred to, but also to exceptional correspondence called forth by political events in connection with the Tonquin affair. Political events had also contributed very much to the development of telegraphic enterprise in the interior of China. During last year several land lines of great importance had been constructed in China; thus from Tientsin to Tungchow, a few miles from Pekin, from Shanghai to Ningpo (in the present year extended to Foochow), &c., whilst at the present moment a line was being built between Canton and Foochow, and between Nankin and Hankow, and lines to Pekin and Paotingfoo were contemplated. The chairman might refer to an interesting but less important matter, viz., that the Company had taken part in the Electrical Exhibition at Vienna, by successfully exhibiting apparatus and instruments manufactured in their own workshops at Copenhagen. During the past year the Company had also come to the conclusion that it would be desirable to issue new share warrants. The coupons on the old warrants had now been exhausted, and as such new sheets would thus at any rate have to be issued, it had been considered advisable to print new complete warrants with the coupon sheets attached, not only because the warrants of 1872 had been gradually dilapidated, but also as objection had been taken to the French translation label which had been affixed to the back of many of the warrants. The share warrants would therefore in future appear not only with the English and Danish, but also with the French text imprinted on the front. From the balance sheet, which had already been placed before the shareholders, it would appear that after the ordinary charges for interest and amortisation of debentures, the payment of the usual 5 per cent. interim dividend during the past year, &c., had been provided for, there remained an amount of £127,033 5s. 2d., which the directors submitted to the meeting to deal with as follows:—£45,833 6s. 8d. to be divided amongst the shareholders as an extra dividend of 3 per cent. (making the dividend for the year, including the interims already paid, 8 per cent.), £55,555 11s. 1d. to be added to the reserve and renewal fund, and £25,644 7s. 5d. to be carried forward to next year's account. In the division of the net earnings of the Company it will have been observed that the exceptional amount of £2,222 4s. 6d. has been allotted to the pension fund of the staff. The object had been to strengthen that fund, in a prosperous year like the past, in order that it may efficiently fulfil the intentions of the Company when the fund was started. It was, however, understood that the extra allowance would be subject to certain changes in the rules and regulations which appear to be necessary. The Company had great regret in announcing that Vice-Admiral Steen Bille had died in the spring of last year. The admiral had consented to act as an auditor from the very formation of the Company, and had since then shown the warmest sympathy in the well-being of the Company. The Company had, in the meantime, requested Mr. J. A. Garde, formerly governor of the Danish West Indian Islands, a gentleman who had always taken a great interest in the Company, to act as shareholders' auditor for the year 1883. Without discussion the report was then unanimously adopted, the accounts were passed, and discharge given to the board of directors. The retiring director, Julius Sick, Esq., was re-elected, A. Berner, Esq., was re-elected, and J. A. Garde, Esq., was elected as shareholders' auditors.

## HAMMOND ELECTRIC LIGHT AND POWER SUPPLY COMPANY (LIMITED).

An extraordinary general meeting of the shareholders of this Company was held at the works, Appold-street, Finsbury, on the 7th inst., for the purpose of confirming the following resolutions which were passed at the extraordinary general meeting held on the 17th ult.:—(1) "That the nominal capital of the Company, which now consists of the sum of £330,000, divided into 66,000 shares of £5 each, be increased to the sum of £525,000, and that this amount be divided into 350,000 shares of the nominal value of £1 10s. each." (2) "That 50,123 shares of the nominal value of £1 10s. each, forming part of the said capital of £525,000, be issued as fully paid up, and that the same be applied in manner following, that is to say: (*a*) 40,133 of the said £1 10s. shares rateably to the present holders of the 40,133 ordinary £5 shares in this Company, (*b*) 7,990 of the said £1 10s. shares to the holders of the 15,980 deferred £5 shares in this Company, and 2,000 of the said £1 10s. shares to the holder of the founder's shares in this Company." (3) "That the directors be empowered to enter into such agreements or contracts as may be necessary for the carrying out of all or any of these special resolutions, and to issue and allot the balance of the authorised nominal capital of the Company from time to time, on such terms and conditions as they in their discretion may think fit." (4) "That an indenture bearing date the 19th day of March, 1884, and made between the Hammond Electric Light and

Digitized by Google

Power Supply Company (Limited), of the one part, and Robert Hammond of the other part, be and the same is hereby ratified and confirmed."

Sir CHARLES L. YOUNG presided, and formally moved the confirmation, *seriatim*, of the resolutions as above.

Mr. F. C. BARKER seconded the motions, and they were carried unanimously.

Mr. ROBERT HAMMOND: I should like to mention that since our last meeting we have got our works for the manufacture of the incandescent lamp into such full operation that we have issued a circular announcing our preparation to supply the trade and others with incandescent lamps of our own make up to 100 volts at a price of 3s. 6d. per lamp net, the price of other makers up to the present time having been 5s.

The proceedings then terminated.

## MAXIM-WESTON ELECTRIC COMPANY (LIMITED).

The annual meeting of the shareholders of this Company was held on the 2nd inst., at the City Terminus Hotel. An extraordinary meeting was also convened (to be held after the annual meeting), to consider resolutions reducing the capital by £100,000, "by cancelling paid up capital which has been lost or is unrepresented by available assets;" and further reducing the capital by £150,000 "by reducing the nominal amount of all the shares in the Company's capital from £1 to 10s. each." We cannot, however, furnish a report of the proceedings, as the representatives of the Press were refused admission to the meeting.

## ELECTRICAL POWER STORAGE COMPANY (LIMITED).

An extraordinary general meeting of this Company was held on Thursday at the offices, Great Winchester-street-buildings, E.C., Sir Daniel Cooper, Bart., in the chair.

Mr. H. DELL (the Secretary) having read the notice convening the meeting,

The CHAIRMAN moved the confirmation of the following resolution, viz.:—"That the capital of the Company be reduced from £800,000, divided into 200,000 shares of £4 each, to £200,000, divided into 200,000 shares of £1 each, and that such reduction be effected by reducing the nominal amount of every share from £4 to £1."

Mr. J. S. SELLON seconded the motion, which was carried unanimously, and a vote of thanks to the chairman and directors terminated the proceedings.
